

Is species richness mediated by functional and genetic divergence?
 A global analysis in birds

LIST OF FIGURES

| | | |
|-----|---|----|
| S1 | Spatial distribution of CO1 samples downloaded from GenBank containing GPS coordinates. | 3 |
| S2 | Relationship between species richness and nearest neighbor distances (<i>left</i>) and convex hull volumes (<i>right</i>) highlighting the variation in grid cells with the corresponding values. | 3 |
| S3 | Global variation in nearest-neighbor distances and convex hull volumes when analyzing only beak traits | 4 |
| S4 | Relationship between within-family species richness and the number of maximally diverse regions of its constituent species. | 5 |
| S5 | Relationship between within-family species richness and mean nearest-neighbor-distance scores (<i>top</i>) and hull size (<i>bottom</i>). | 6 |
| S6 | Relationship between within-family species richness and packing (<i>left</i>) and overdispersion (<i>right</i>) when only analyzing beak traits. | 7 |
| S7 | Model-averaged path analysis results for nearest-neighbor distances and convex hull volumes respectively | 7 |
| S8 | Model-averaged path analysis results for nearest-neighbor distances and convex hull volumes respectively when only analyzing beak traits. | 8 |
| S9 | Relationship between within-family species richness and packing (<i>left</i>) and overdispersion (<i>right</i>) when calculated using multivariate disparity. | 9 |
| S10 | Global variation in nucleotide diversity (π) between the six genes analyzed in this study. | 10 |
| S11 | Relationship between family species richness and the difference in nucleotide diversity (π) between allopatric and sympatric species excluding one outlier (Certhiidae). | 10 |

LIST OF TABLES

| | | |
|----|---|----|
| S1 | Estimates of the effect of family diversity on nearest neighbor distances and convex hull volumes while accounting for shared evolutionary history. | 11 |
| S2 | Comparison of log-transformed nucleotide diversity (π) between different geographic states. | 12 |
| S3 | Correlation between branch length and nucleotide diversity across the six genes analyzed in this study. | 12 |

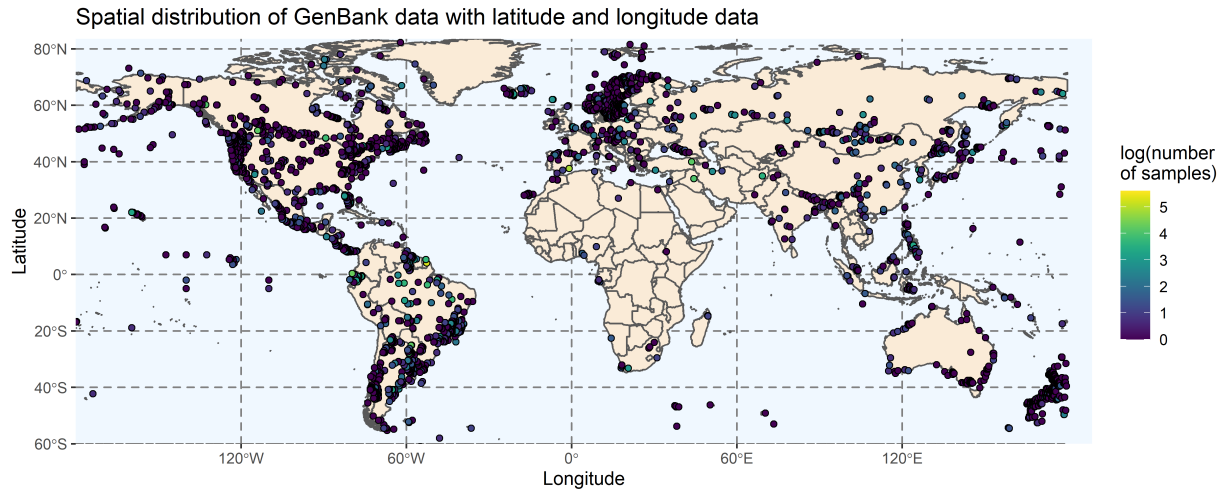

Figure S1: Spatial distribution of CO1 samples downloaded from GenBank containing GPS coordinates.

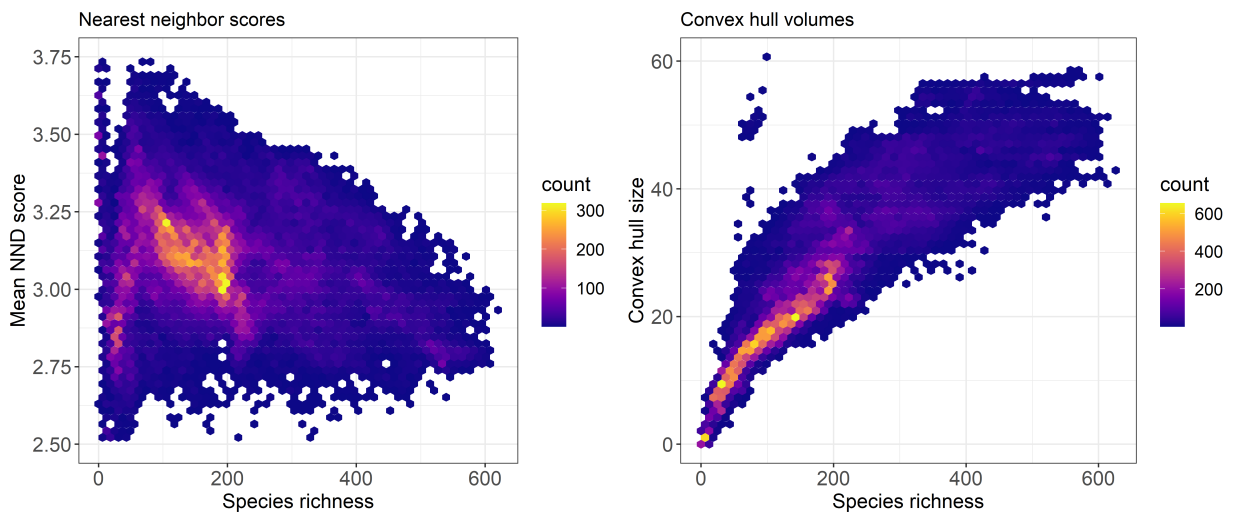

Figure S2: Relationship between species richness and nearest neighbor distances (*left*) and convex hull volumes (*right*) highlighting the variation in grid cells with the corresponding values.

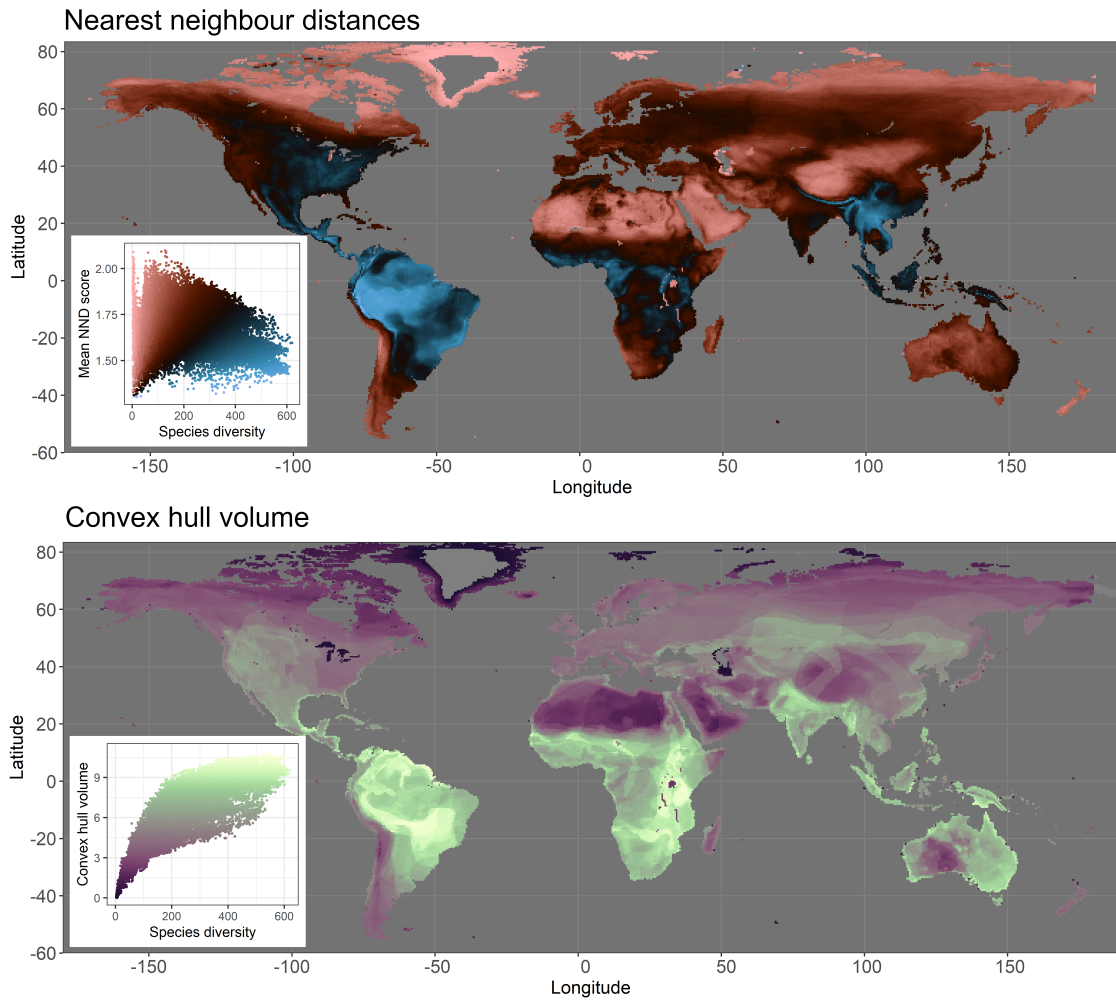

Figure S3: Global variation in nearest-neighbor distances and convex hull volumes when analyzing only beak traits. Inset panels in both images show the relationship between the corresponding variable and species richness across the globe.

Figure S4: Relationship between within-family species richness and the number of maximally diverse regions of its constituent species.

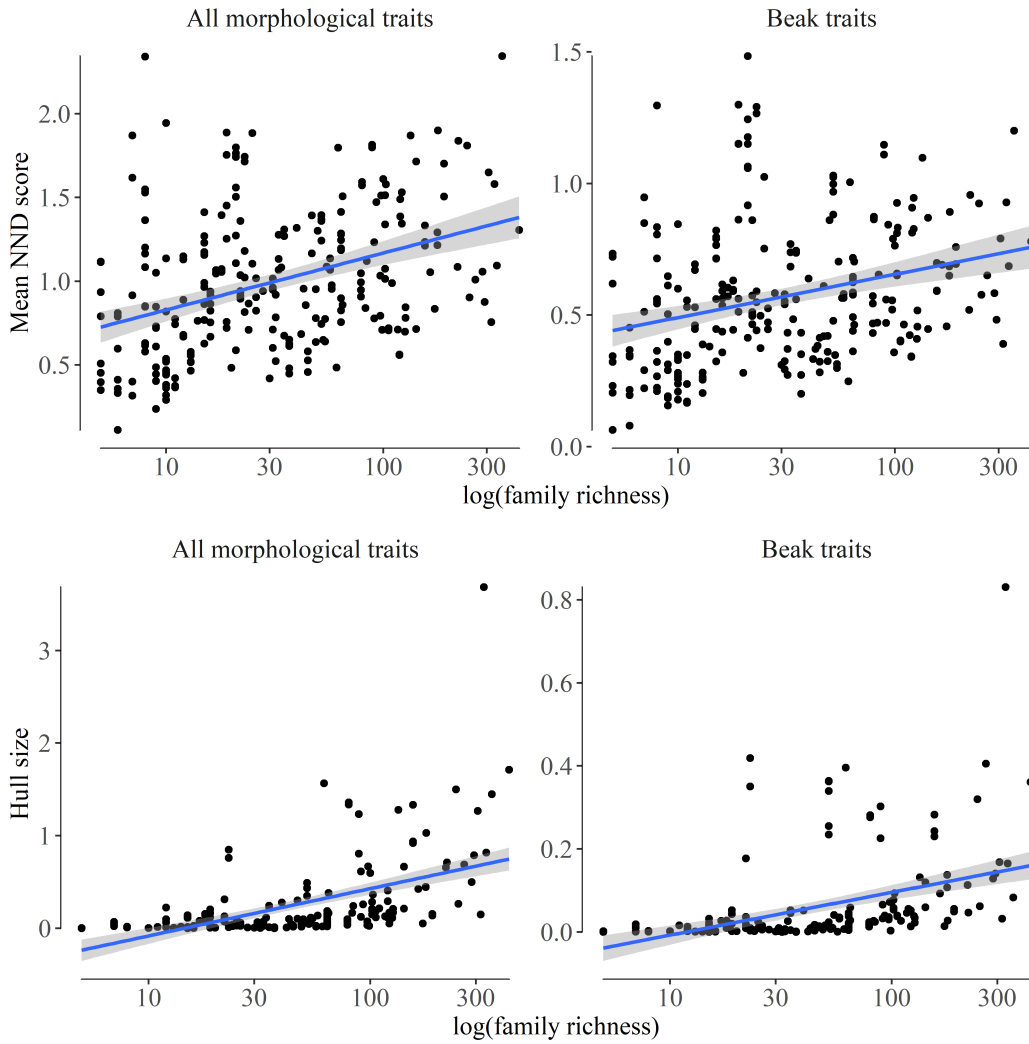

Figure S5: Relationship between within-family species richness and mean nearest-neighbor-distance scores (*top*) and hull size (*bottom*).

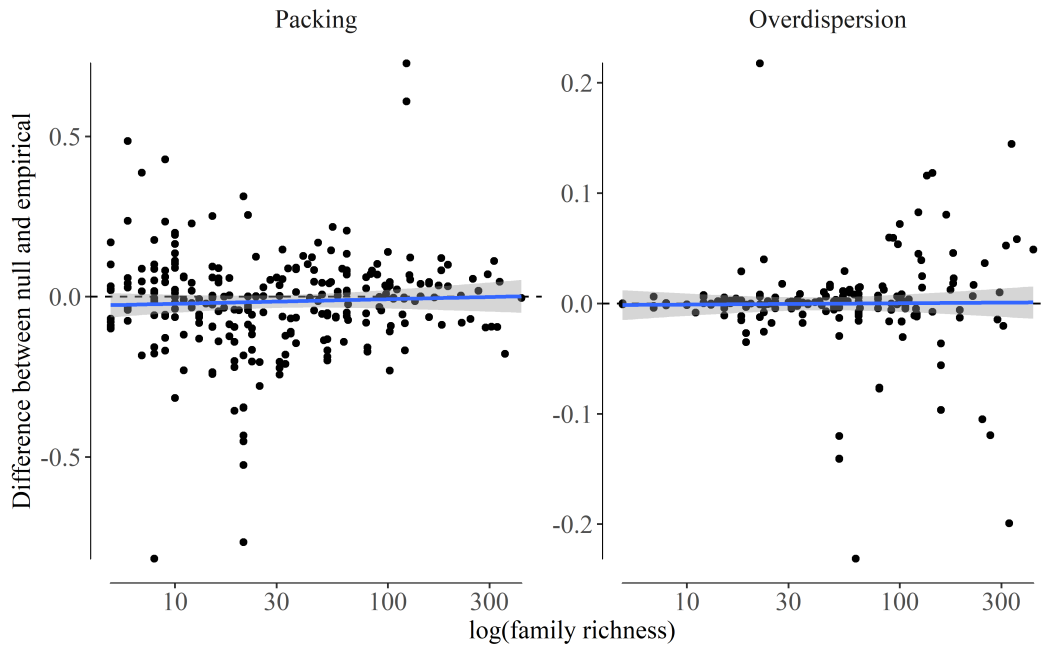

Figure S6: Relationship between within-family species richness and packing (*left*) and overdispersion (*right*) when only analyzing beak traits.

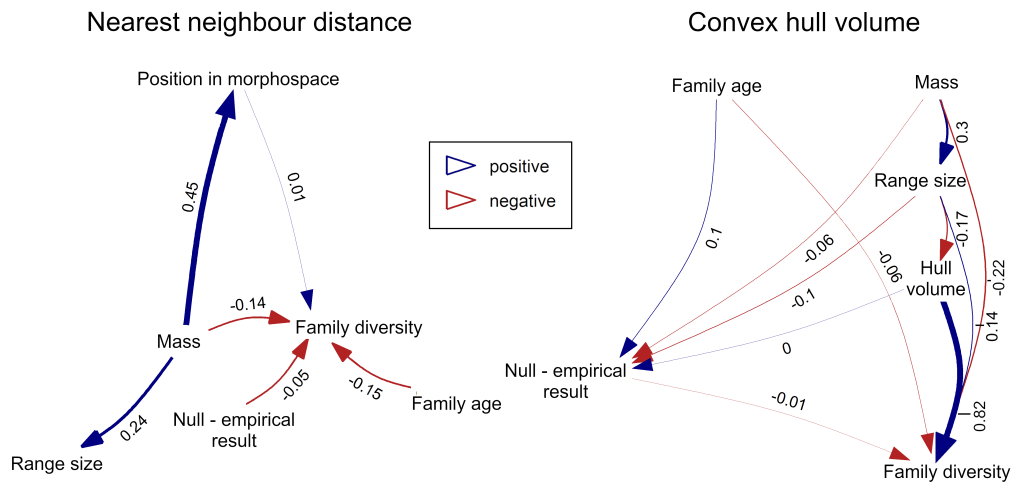

Figure S7: Model-averaged path analysis results for nearest-neighbor distances and convex hull volumes respectively. “Null – empirical result” is the difference between the observed value for the area of maximum species richness minus the mean value from a random distribution of species.

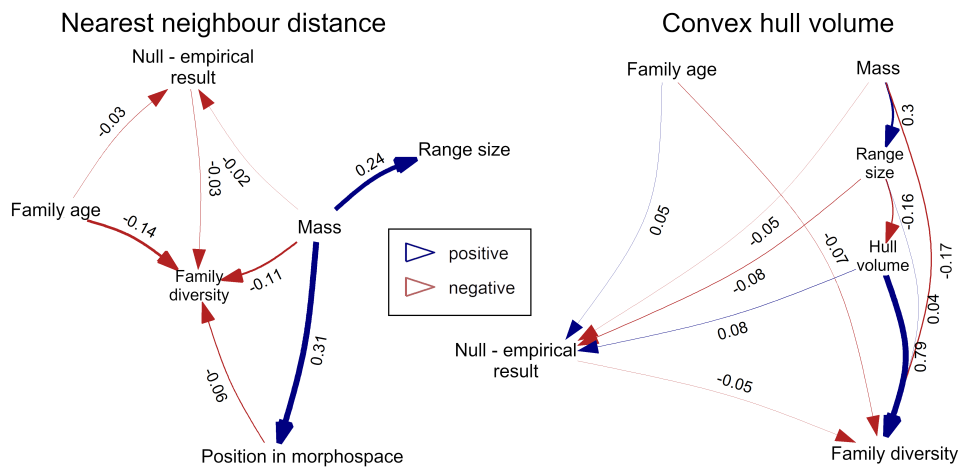

Figure S8: Model-averaged path analysis results for nearest-neighbor distances and convex hull volumes respectively. Null – empirical result reflects the difference between the observed value for the area of maximum species richness minus the mean value from a random distribution of species.

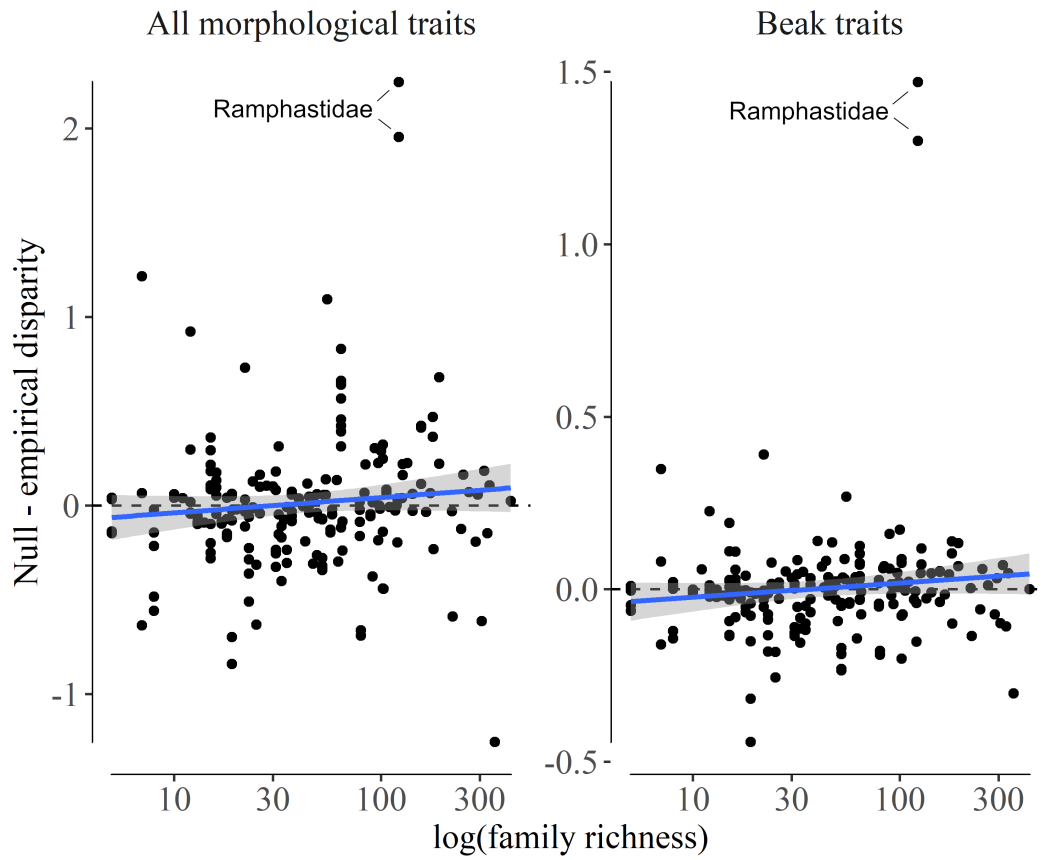

Figure S9: Relationship between within-family species richness and packing (*left*) and overdispersion (*right*) when calculated using multivariate disparity.

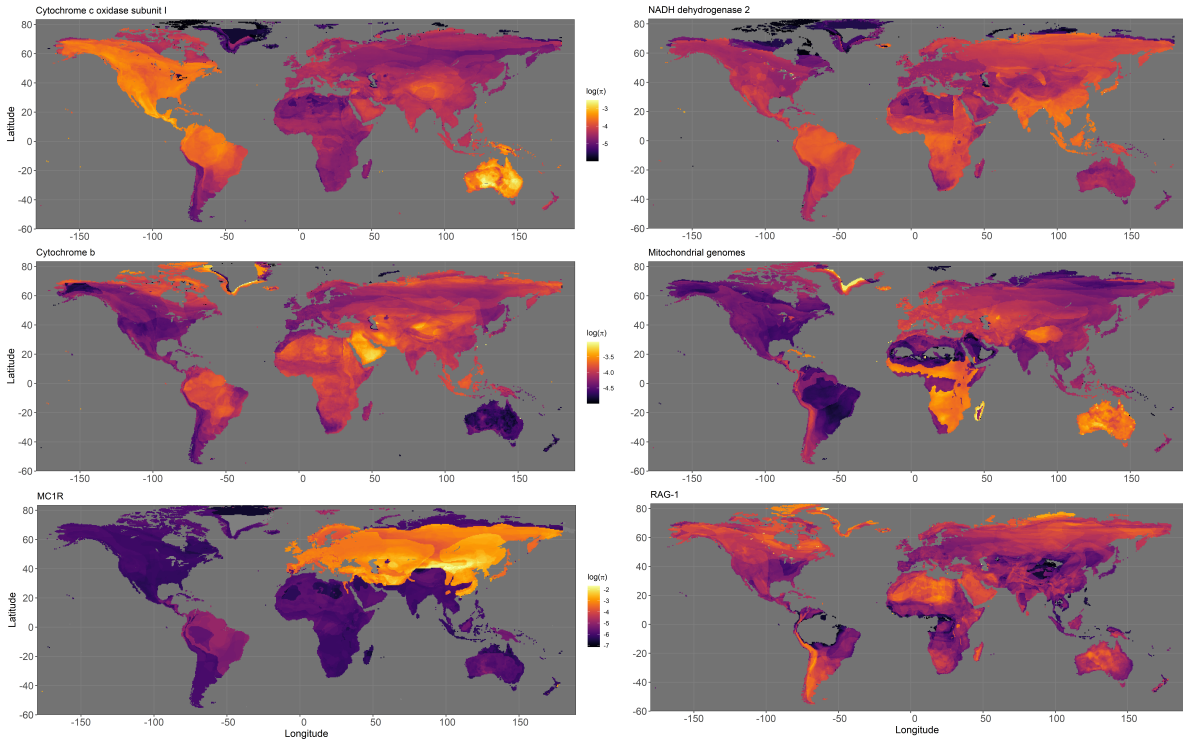

Figure S10: Global variation in nucleotide diversity (π) between the six genes analyzed in this study.

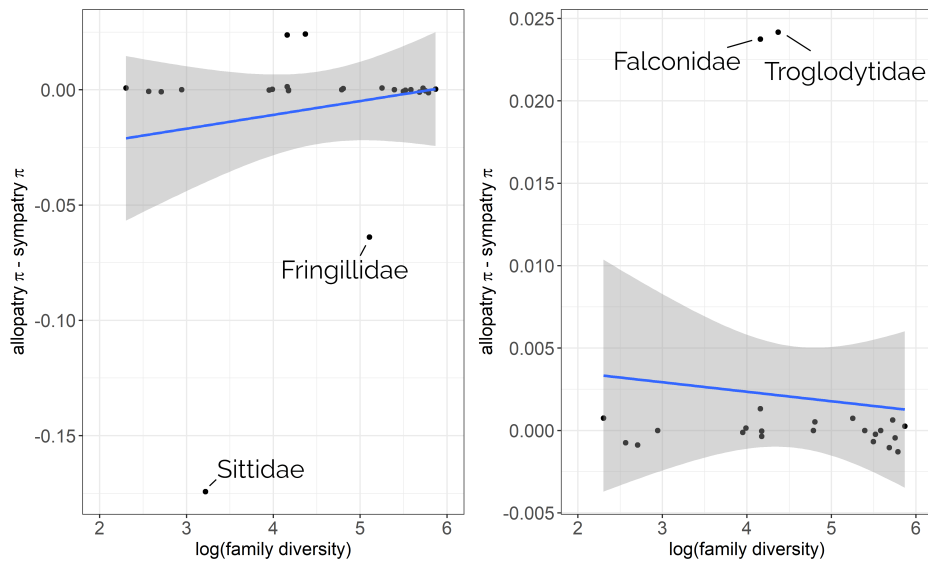

Figure S11: Relationship between family species richness and the difference in nucleotide diversity (π) between allopatric and sympatric species excluding one outlier (Certhiidae). The right-hand panel shows the relationship with the exclusion of the families Sittidae and Fringillidae.

| Analysis | Morphological data | Estimate | p | λ |
|---------------------------|---------------------------|-----------------|----------|-----------|
| Nearest neighbor distance | All morphological traits | -0.004 | 0.75 | 1e-07 |
| | Beak traits | -0.002 | 0.85 | 1e-07 |
| Convex hull volume | All morphological traits | -0.002 | 0.92 | 1e-07 |
| | Beak traits | 0.001 | 0.74 | 1e-07 |

Table S1: Estimates of the effect of family diversity on nearest neighbor distances and convex hull volumes while accounting for shared evolutionary history. λ is the estimated phylogenetic signal from each model respectively.

| Comparison | Gene | t | p | Effect size | Magnitude | n1 | n2 | Where π is largest |
|---|-------|-------|------|-------------|------------|------|------|------------------------|
| Allopatry (defined using sister species) | CO1 | 0.16 | 0.87 | 0.01 | Negligible | 800 | 1405 | Allopatry |
| | CYTB | -3.00 | 0.00 | -0.13 | Negligible | 866 | 1178 | Sympatry |
| | ND2 | -4.91 | 0.00 | -0.20 | Small | 1059 | 1381 | Sympatry |
| | mtDNA | 0.31 | 0.76 | 0.05 | Negligible | 84 | 102 | Allopatry |
| | RAG1 | -1.31 | 0.19 | -0.19 | Negligible | 104 | 95 | Sympatry |
| | MC1R | 0.58 | 0.57 | 0.13 | Negligible | 37 | 47 | Allopatry |
| Allopatry (defined using all confamilial species) | CO1 | 0.97 | 0.34 | 0.20 | Negligible | 27 | 2081 | Allopatry |
| | CYTB | -4.47 | 0.00 | -0.58 | Moderate | 52 | 1992 | Sympatry |
| | ND2 | -0.85 | 0.37 | -0.12 | Negligible | 49 | 2310 | Sympatry |
| | mtDNA | -2.84 | 0.04 | -1.23 | Large | 5 | 175 | Sympatry |
| | RAG1 | 1.20 | 0.35 | 0.78 | Moderate | 3 | 193 | Allopatry |
| | MC1R | -4.54 | 0.00 | -0.74 | Moderate | 2 | 76 | Sympatry |
| Tropical and temperate species | CO1 | 7.07 | 0.00 | -0.49 | Small | 286 | 602 | Tropical |
| | CYTB | 6.43 | 0.00 | -0.46 | Small | 238 | 831 | Tropical |
| | ND2 | 5.52 | 0.00 | -0.41 | Small | 213 | 1157 | Tropical |
| | mtDNA | 0.06 | 0.95 | -0.01 | Negligible | 33 | 45 | Temperate |
| | RAG1 | -1.63 | 0.12 | 0.47 | Small | 22 | 45 | Temperate |
| | MC1R | -1.14 | 0.26 | 0.42 | Small | 16 | 14 | Temperate |

Table S2: Comparison of log-transformed nucleotide diversity (π) between different geographic states. t is the result of a two-sided t-test, and p the associated significant of the test. Effect size is Cohen's D estimate of effect size, with magnitude the interpretation of the effect size. n1 and n2 refer to the sample sizes for allopatry/sympatry and temperate/tropical respectively. The final column describes which geographic state has the largest mean value of π .

| Gene | Correlation | Sample size |
|-------|-------------|-------------|
| CO1 | -0.02 | 2434 |
| CYTB | 0.09 | 2401 |
| ND2 | 0.05 | 2617 |
| mtDNA | 0.16 | 199 |
| RAG1 | 0.05 | 208 |
| MC1R | 0.11 | 85 |

Table S3: Correlation between branch length and nucleotide diversity (π) across the six genes analyzed in this study. Sample size is the number of species used to test the correlation. Species with π scores of 0 were excluded as the data were required to be log-transformed prior to analysis.
