(57) **ABSTRACT**

The structures of Edema Factor alone and Edema Factor bound to calmodulin without substrate has been crystallized and its structure determined by x-ray crystallography. Based upon these crystal structures, a method assaying for inhibitors of infection by a bacteria is presented which comprises obtaining a potential inhibitor, obtaining a calmodulin activated adenylyl cyclase exotoxin, obtaining calmodulin, admixing the potential inhibitor, the exotoxin, and the calmodulin, and assaying to determine whether or not the potential inhibitor inhibits production of cAMP by exotoxin.

METHODS AND COMPOSITIONS RELATING TO ANTHRAX PATHOGENESIS

This application claims priority to, and specifically incorporates herein by reference, U.S. Provisional Application Ser. No. 60/336,762 filed Nov. 2, 2001.

This invention was made with government support under grant number GM53459, GM62458, and DA05778 awarded by the National Institutes of Health. The government has certain rights in the invention.

FIELD OF THE INVENTION

The present invention generally relates to crystalline Edema Factor (EF) without substrate, crystalline Edema Factor-calmodulin complex without substrate and the structures of Edema Factor without substrate and Edema Factor-calmodulin complex as determined by x-ray crystallography. Specifically, this invention relates to the use of the structures of Edema Factor without substrate, Edema Factor-calmodulin complex, and any of its homologues, mutants and/or co-complexes of such structures to design modulators of calmodulin activation of Edema Factor.

BACKGROUND OF THE INVENTION

Many infectious organisms increase the internal cyclic AMP (cAMP) levels of infected host cells. Whereas, some do this through chemical modification of heterotrimeric G-proteins, at least four bacteria, *Bordetella pertussis* (Whooping cough), *Pseudomonas aeruginosa* (various nosocomial infections), *Yersinia pestis* (plague) and *Bacillus anthracis* (Anthrax) accomplish this by producing toxins with adenylyl cyclase activity (Leppla, 1982; Ladant and Ullmann, 1999; Yahr et al., 1998; Shevchenko and Mishankin, 1987; Parkhill et al., 2001; Michankin et al., 1992).

Bacillus anthracis, the bacterium responsible for anthrax is estimated to be responsible for 20,000-100,000 cases of naturally contracted anthrax per year, worldwide. Anthrax may cause death within 24 hours, preceded only by nondescript, flu-like symptoms (Hanna 1998). In part, because the spore form of the bacterium is easily stored for long periods, anthrax has undergone significant development as a biological weapon.

Bacillus anthracis defeats the host defense system by secreting three exotoxins, protective antigen, lethal factor and Edema Factor (EF) (Baillie and Read, 2001; Dixon et al., 1999; Mock and Fouet, 2001). Protective antigen, a pH-dependent transporter, binds and transports both lethal factor and Edema Factor into the cytosol of eukaryotic cells. Lethal factor, a zinc metalloprotease, cleave and inactivate mitogen-activated protein kinase kinase and possibly other cellular proteins in the macrophage (Duesbery et al., 1998). This results in the release of tumor necrosis factor α and interleukin-1 β which are partly responsible for sudden death in systemic anthrax. Edema Factor, a calmodulin (CaM)-activated adenylyl cyclase, can increase the level of intracellular cyclic AMP to a pathologic level, upsetting water homeostasis (Baillie and Read, 2001; Dixon et al., 1999; Mock and Fouet, 2001). EF is responsible for the massive Edema seen in cutaneous anthrax and impaired neutrophil function in systematic infection.

Edema Factor is a 92.5 kDa protein that can be roughly divided into two distinct domains (Leppla, 1998). The N-terminal 250 amino-acid region of EF is centrally involved in EF's association with protective antigen and entrance into host cells (Labruyere et al., 1990; Drum et al. 2000). The

C-terminal, 510 amino acid region (amino acids 291-800) has calmodulin activated adenylyl cyclase activity (Labruyere et al., 1990; Drum et al. 2000). After gaining access to the cytoplasm, Edema Factor binds calmodulin at the resting calcium concentration and is thus, activated to produce unregulated levels of cAMP within the cytosol of the host cell (Leppla, 1984; Leppla, 1982). The rate of ATP conversion to cAMP by Edema Factor is two to three orders of magnitude greater than membrane-bound eukaryotic adenylyl cyclases (Labruyere et al., 1990; Tang et al., 1991).

Calmodulin is a 16.5 kDa prototypic calcium sensor involved in modulation of many intracellular processes including synaptic plasticity, control of gene transcription, ion conductivities, vesicular fusion, and learning (Deisseroth et al., 1998; DiAntonio, 2000; Ehlers and Augustine, 1999; Peters and Mayer, 1998). Calmodulin transduces intracellular calcium signals via two globular domains connected by a flexible, central α -helix. Each globular domain is composed of two helix-loop-helix "EF-hand" calcium binding motifs (Babu et al., 1985; Chattopadhyaya et al., 1992; Wilson and Brunger, 2000). Calcium binding shifts these domains from a mainly hydrophilic, closed state, to an open conformation exposing a large, hydrophobic binding pocket (Kuboniwa et al., 1995; Finn et al., 1995). An exceptionally broad array of effector molecules are regulated through interaction with CaM, including enzymes that control diffusible messengers and that alter the state of protein phosphorylation, molecules that modulate ion conductivity, and cytoskeletal proteins (Eldik and Watterson, 1998). Although the structure of CaM has been solved in complex with an assortment of effector fragments, none of these complexes has contained active enzymes or peptide fragments larger than 10 kDa.

The structural characterization of the adenylyl cyclase domain of EF holds promise for insight in several different areas. First, secreted adenylyl cyclases compose a multigene family of exotoxins produced by at least four distinct pathogenic bacteria, *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa* and *Yersinia pestis*. The structural features peculiar to this homologous family may provide insight into overall functional themes of toxin activation and inhibition. Second, the catalytic rate of EF is approximately one hundred times faster than that of membrane bound adenylyl cyclases whose catalytic core domain has been structurally determined (Tesmer et al., 1997). With no sequence homology detectable between the two adenylyl cyclase families, a structural understanding of the active site of EF may yield a novel fold used for the cyclization of ATP or a variant on the di-metal mediated catalysis used by membrane-bound adenylyl cyclases (Tesmer et al., 1999). Third, the mechanism of activation with which the binding of calmodulin regulates the production of cyclic AMP in some pathogenic bacteria may hold implications for inhibitory strategies of the toxin as well as structural themes applicable to other calmodulin binding enzymes.

The inventors recently reported biochemical characterization of EF/CaM interaction (Drum et al., 2000). Drum et al. provided a detailed look of the interaction between CaM and EF, and suggested a catalytic mechanism for converting ATP to cAMP that is different from that seen in previously solved adenylyl cyclases (Tesmer et al., 1999). To understand the molecular detail in the catalytic site of EF and the interaction of EF with CaM, the inventors have solved two structures; the structure of EF without CaM or substrate, and the structure of EF with CaM, but without substrate. Comparison of these structures, along with mutational analysis reveals that the key step in CaM activation of EF is the removal of an inhibitory domain which is distant from the active site and the stabili-

zation of a catalytic loop. Such understanding of this mechanism not only gives a first molecular insight into how CaM activates EF, but also provides potential avenues for modulating CaM activation of EF.

The present invention discloses these structures and also discloses various methods of screening assays to identify small molecules that modulate activation of EF by CaM and EF alone.

Adenylyl cyclase toxins are known to be secreted by two other human pathogens, *Bordetella pertussis* (CyaA) and *Pseudomonas aeruginosa* (ExoY) which cause whooping cough and 10-20% of hospital-acquired infections, respectively (Ladant and Ullmann, 1999; Yahr et al., 1998). Immuno-compromised patients, such as, cystic fibrosis and AIDS patients, are particularly vulnerable. Since these pathogens can be hospital acquired, they are likely to harbor many antibiotic resistance. Thus, many antibiotics can be ineffective in fighting against such infections. Accordingly, better drugs against these pathogens will likely be useful to block the toxic effects caused by the infection of these pathogens.

Also, biochemical studies have shown that *Yersinia pestis*, the bacterium that causes plague, also secretes an adenylyl cyclase toxin and genome sequence identified a gene in *Yersinia pestis* for such a toxin (Shevchenko and Mishankin, 1987; Parkhill et al., 2001; Michankin et al., 1992). *Yersinia pestis* is primarily a rodent pathogen which is usually transmitted subcutaneously to humans by the bite of an infected flea.

The structure of Edema Factor discovered by the inventors can be useful in discovering small molecules that can be useful against the infection of *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa* and *Yersinia pestis*.

SUMMARY OF THE INVENTION

The present invention overcomes the deficiencies in the art by providing methods of assaying for an inhibitor of infection by a bacteria by obtaining a potential inhibitor, a calmodulin activated adenylyl cyclase exotoxin, calmodulin and admixing the potential inhibitor, the exotoxin and the calmodulin and then assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin. As used herein, the terms "inhibitor," "inhibit," and "inhibition" are defined as a complete inactivation or reduced activation of exotoxin activity. The present invention also provides for methods of assaying for an inhibitor of the bacterial infections *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa* and/or *Yersinia pestis*. In certain embodiments, the exotoxin is Edema factor and its sequence homologs from *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa* and/or *Yersinia pestis*. The present invention also contemplates obtaining the potential inhibitor comprising selecting the potential inhibitor by structural based inhibitor discovery. In other embodiments, the calmodulin activated adenylyl cyclase exotoxin is Edema Factor from *Bacillus anthracis*. In yet another embodiment, the calmodulin activated adenylyl cyclase exotoxin is a homolog of *Bacillus anthracis* Edema Factor from *Pseudomonas aeruginosa* or *Yersinia pestis*.

In other embodiments, the potential inhibitor is a protein, a small molecule, a modified nucleotide, or an antibody. The potential inhibitor is obtained by designing the potential inhibitor to form non-covalent bonds with amino acids of Edema Factor, calmodulin, Edema Factor/calmodulin complex with substrate, and/or Edema Factor/calmodulin complex without substrate, based upon the crystal structure of Edema Factor, calmodulin, Edema Factor/calmodulin com-

plex with substrate, and/or Edema Factor/calmodulin complex without substrate. In certain embodiments, the potential inhibitor is designed to bind the adenylyl cyclase domain of Edema Factor, the active site of the adenylyl cyclase domain of Edema Factor, the calmodulin binding domain of Edema Factor, or the Edema Factor binding domain of calmodulin. In another embodiment, the potential inhibitor is designed to bind the amino acid Arg³²⁹, Lys³⁴⁶, Lys³⁵³, Asp⁴⁹¹ and/or Asp⁴⁹³, His⁵⁷⁷, His³⁵¹, Lys⁵²⁵, Lys³⁷², Thr⁵⁴⁸, Thr⁵⁷⁹, As⁵⁸³, Glu⁵⁸⁸, Asp⁵⁹⁰, Asp⁶⁴⁷, Asn⁶³⁹, and/or Pro⁵⁸⁷.

In other embodiments, the potential inhibitor is designed to bind at least 1, 2, 5, 10, 20, 30, 40, 50, 60, 75, 100, 150, 200 and/or 508 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of the adenylyl cyclase domain of Edema Factor, which is found at approximately amino acids 291-800 of Edema Factor. As used herein, "any integer derivable therein" means a integer between the numbers described in the specification, and "any range derivable therein" means any range selected from such numbers or integers. In other embodiments, the potential inhibitor will bind the adenylyl cyclase domain of Edema Factor, which is found at approximately amino acids 291-800 of Edema Factor.

In one embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20, 40 and/or 57 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of the C_A domain of Edema Factor, which is found at approximately amino acids 291-349 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind the C_A domain of Edema Factor, which is found at approximately amino acids 291-349 of Edema Factor.

In still another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20, and/or 41 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of the C_A domain of Edema Factor, which is found at approximately amino acids 490-622 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind the C_A domain of Edema Factor, which is found at approximately amino acids 490-622 of Edema Factor.

In another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20, 40, 50, 100 and/or 138 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of the C_B domain of Edema Factor, which is found at approximately amino acids 350-489 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind the C_B domain of Edema Factor, which is found at approximately amino acids 350-489 of Edema Factor.

In another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20, 30, 40, 50, 75, 100 and/or 139 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of the helical domain of Edema Factor, which is found at approximately amino acids 660-800 of Edema Factor. In still another embodiment, the potential inhibitor is designed to bind the helical domain of Edema Factor, which is found at approximately amino acids 660-800 of Edema Factor.

In still another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20 and/or 35 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of an extended linker that connects the helical domain to the C_A of Edema Factor, which is found at approximately amino acids 623-659 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind the extended linker that connects the

5

helical domain to the C₄ of Edema Factor, which is found at approximately amino acids 623-659 of Edema Factor.

In yet another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20 and/or 48 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of Switch A, which is found at approximately amino acids 502-551 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind Switch A, which is found at approximately amino acids 502-551 of Edema Factor.

In still another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10 and/or 12 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of Switch B, which is found at approximately amino acids 578-591 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind Switch B, which is found at approximately amino acids 578-591 of Edema Factor.

In another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20 and/or 28 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of Switch C, which is found at approximately amino acids 630-659 of Edema Factor. In still another embodiment, the potential inhibitor is designed to bind Switch C, which is found at approximately amino acids 630-659 of Edema Factor.

In yet another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20 and/or 34 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 501-536 of Edema Factor. In another embodiment, the potential inhibitor is designed to bind a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 501-536 of Edema Factor.

In still another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10 and/or 13 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 620-634 of Edema Factor. In one embodiment, the potential inhibitor is designed to bind a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 620-634 of Edema Factor.

In another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15, 20 and/or 24 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 647-672 of Edema Factor. In one embodiment, the potential inhibitor is designed to bind a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 647-672 of Edema Factor.

In yet another embodiment, the potential inhibitor is designed to bind at least 2, 5, 10, 15 and/or 16 or more contiguous amino acids including any integer derivable therein, and any range derivable therein, of a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 690-707 of Edema Factor. In one embodiment, the potential inhibitor is designed to bind a domain of Edema Factor that binds calmodulin, which is found at approximately amino acids 690-707 of Edema Factor.

In another embodiment, the potential inhibitor is designed to bind the adenylyl cyclase domain of Edema Factor when Edema Factor is bound to calmodulin. In still another

6

embodiment, the potential inhibitor is designed to bind the adenylyl cyclase domain of Edema Factor when Edema Factor is not bound to calmodulin. In another embodiment, the potential inhibitor is designed to bind the active site of the adenylyl cyclase domain of Edema Factor. In a further embodiment, the potential inhibitor is designed to bind the active site of the adenylyl cyclase domain of Edema Factor when Edema Factor is bound to calmodulin. In still a further embodiment, the potential inhibitor is designed to bind the calmodulin binding domain of Edema Factor. In yet another embodiment, the potential inhibitor is designed to bind the calmodulin binding domain of Edema Factor when Edema Factor is not bound to calmodulin. In still another embodiment, the potential inhibitor is designed to bind the calmodulin binding domain of Edema Factor when Edema Factor is bound to calmodulin. In another embodiment, the potential inhibitor is designed to bind the Edema Factor binding domain of calmodulin. In still another embodiment, the potential inhibitor is designed to bind the Edema Factor binding domain of calmodulin when Edema Factor is not bound to calmodulin. In another embodiment, the potential inhibitor is designed to bind the Edema Factor binding domain of calmodulin when Edema Factor is bound to calmodulin.

In another aspect of this invention, there is a process of identifying an inhibitor of a bacterial infection by obtaining a potential inhibitor, a calmodulin activated adenylyl cyclase exotoxin, and calmodulin and admixing the potential inhibitor, the exotoxin and the calmodulin and then assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin.

In yet another embodiment of present invention, there is a pharmaceutical composition comprising an inhibitor of a bacterial infection identified by a process comprising obtaining a potential inhibitor, a calmodulin activated adenylyl cyclase exotoxin and calmodulin and admixing the potential inhibitor, the exotoxin, and the calmodulin and then assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin.

In still another embodiment of the present invention, there is a method of inhibiting pathogenesis of a bacterial infection comprising; obtaining a pharmaceutical composition comprising an inhibitor of a bacterial infection identified by a process comprising obtaining a potential inhibitor, a calmodulin activated adenylyl cyclase exotoxin, and calmodulin, and then admixing the potential inhibitor, the exotoxin, and the calmodulin and assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin and then administering an effective amount of the pharmaceutical composition to a subject.

In yet another embodiment, there is a method of assaying for an inhibitor of infection by a bacteria comprising obtaining a potential inhibitor, obtaining an adenylyl cyclase exotoxin, admixing the potential inhibitor and the exotoxin and assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin. The bacterial infection can be *Pseudomonas aeruginosa* or *Yersinia pestis*. In other embodiments, the activated adenylyl cyclase exotoxin is an Edema Factor homolog. The Edema Factor homolog can be from *Pseudomonas aeruginosa* (ExoY) or *Yersinia pestis*. The adenylyl cyclase exotoxin can also be a homolog of *Bacillus Anthracis* Edema Factor from *Pseudomonas aeruginosa* or *Yersinia pestis*. The present invention also contemplates obtaining the potential inhibitor comprising selecting the potential inhibitor by structural based inhibitor discovery.

BRIEF DESCRIPTION OF THE FIGURES

The patent or application file contains at least one drawing executed in color. Copies of this patent or patent application publication with color drawing(s) will be provided by the Office upon request and payment of the necessary fee.

FIG. 1A and FIG. 1B Secondary structure representation of EF alone FIG. 1A and EF-CaM-3'dATP complex FIG. 1B. CaM (red) is held on one side by a fingerlike projection of CA, and on the other by switch C (magenta), and by the helical domain (yellow). Switch A and switch B is colored cyan and orange, respectively. The ATP analog and metal (purple) are bound between the two domains CA and CB (both colored green) which form the active site. In EF alone structure, the last two helices, P and Q (a.a. 771-799, white), which are not part of the CaM interface or the active site, are swapped between two EF molecules in the EF alone structure. This swap is unlikely to be physiological relevant since EF is a monomer based on gel exclusion column.

FIG. 2 Sequence alignment of EF (SEQ ID NO. 1) and CyaA (SEQ ID NO. 2). On the top of sequence shows the second structure assignment of EF alone. The second structures of EF-CaM that differ from EF alone are shown on the top of EF alone structure when applicable. Residues that contact the nucleotide substrate are highlighted red. Molecular contacts are shown as the colored boxes below the sequences. CaM contact residues are colored in five shades of red. These residues are colored in 20 Å² increments, based on their CaM contact area. The lightest colored boxes indicate less than 20 Å² of contact area, the darkest colored boxes indicate that more than 80 Å² are buried by the CaM interaction. Inter-domain indicates residues that are involved inter-domain interaction between the helical domain and the remainder of EF in the EF alone structure. They are colored based on their contact region including switch A (cyan), switch C (magenta), C_A region (green), and helical domain (yellow). /////

FIG. 3A and FIG. 3B Space filling representation of EF alone FIG. 3A and CaM-complexed EF FIG. 3B. Switch A, B and C atoms are colored cyan, orange, and yellow, respectively. Residues which contact CaM are red.

FIG. 4A, FIG. 4B, and FIG. 4C Switch movement results in catalytic activation. This view looks down from the top of the molecule relative to FIG. 1. FIG. 4A Ball-and-stick representations for the active site of EF alone catalytic site. FIG. 4B EF-CaM complex without nucleotide, and FIG. 4C EF-CaM complex with 3'dATP. SO₄ and 3'dATP in EF alone and EF-CaM-3'dATP complex, respectively are colored black and yellow, respectively. Metal ions are colored gray. Residues from switch A (540-551), switch B (578-592), switch C (634-642) and C_A/C_B outside of the switch regions are shown in cyan, orange, magenta, and green, respectively.

FIG. 5A, FIG. 5B, FIG. 5C, and FIG. 5D Active site of EF and its comparison with mAC. FIG. 5A Ball-and-stick representation of the EF active site. Secondary structure elements and amino acid residues are colored green and blue, respectively. 3'd-ATP and metal are colored black and gray, respectively. FIG. 5B Proposed mechanism of catalysis of EF. For the clarity, only residues that are directly involved in 3' O⁻ to α-phosphate nucleophilic attack are shown. FIG. 5C Ball-and-stick representation of the mAC active site. Secondary structure elements of C1a and C2a are colored green and yellow, respectively. Amino acid residues, ATPαS, and metals are colored blue, black, and gray, respectively. The O4', C4', and α-P of ATPαS is oriented similar to those of 3'd-ATP in FIG. 5A for comparison. FIG. 5D Secondary structures of the EF catalytic core and the mAC catalytic core. C1a and C2a

of mAC are colored green and yellow, respectively. The view of EF and mAC is the same as in FIG. 5A and 5C, respectively.

FIG. 6A and FIG. 6B CaM binding of EF. This view is rotated 90° relative to FIG. 1. FIG. 6A Ribbon representation of CaM and EF. CaM is colored red. Switch A, switch C, the helical domain and C_A/C_B outside of the switch regions are shown in cyan, magenta, yellow, and green, respectively. FIG. 6B Mutational analysis of EF residues that contact CaM. The adenyl cyclase assay was performed with EF (5 ng), K525A (5 ng), and D647A (50 ng) at 30° C. for 10 min in the present of 5 mM ATP, 10 mM MgCl₂ and 0.05 mM CaCl₂.

FIG. 7A, FIG. 7B, FIG. 7C, FIG. 7D, and FIG. 7E Comparison of CaM conformations and of CaM/effector contacts. FIG. 7A Ribbon representations of CaM alone, FIG. 7B CaM in complex with effector derived peptides from myosin light chain kinase, FIG. 7C the calcium sensitive potassium ion channel, and FIG. 7D Edema Factor. The C-terminal domain (red) of CaM is aligned based on helix VI of CaM. The CaM central helix and N-terminal domains are colored orange, and the effector peptides are colored blue. In FIG. 7E, the sequence and secondary structure of CaM is shown, with calcium-binding sites indicated, and calcium-binding residues colored red. The boxes beneath the CaM sequence indicate the effector contact area of each residue in the various structures, using the same coloring scheme as in FIG. 2. The PDB codes for the structures used in making this figure are 1CLL, 1CDL, 1CKK, 1CDM, and 1G4Y for CaM alone, and complexes with myosin light chain kinase, CaM dependent protein kinase, CaM dependent protein kinase II, and the gating domain of the small conductance potassium channel, respectively. The helix designations above the CaM sequence are based on the 1CLL CaM structure.

FIG. 8 Self-rotation function with the 1222 crystal form of EF3/calmodulin using native data between 15.0-4.0 Å and a 30.0 Å radius of integration at k=120° section. The plot was contoured starting at 15 s with an interval of 3 s. This figure was calculated using GLRF (Tong, 1990).

FIG. 9 FOM weighted Fo map calculated from solution of the combined phases from selenomethionine, uranium, and lead. The helices from each of the three non-crystallographically related molecules in the asymmetric unit are shown. This figure was calculated using Xtalview (McRee, 1992).

FIG. 10 Depiction of homologous secondary structure elements between the EF/CaM and c-Cb1/UbcH7 complexes. Regions of structure homology are colored by blue (segments of EF C_B and UbcH7), green (segments of EF C_A and c-Cb1-SH2), red (CaM c-terminal and c-Cb1 "EF-hand" domain), and yellow (helical domains of EF and c-Cb1). The RING domain (residues 327-382) of c-Cb1 and the CaM N-terminal domain (residues 82-147) are removed for clarity.

DETAILED DESCRIPTION OF THE INVENTION

I. The Present Invention

There have been suggestions and hypothetical models created to explain the mechanism by which calmodulin (CaM) interacts with and activates Edema Factor. While these suggestions have some accuracy, they have not proven beneficial for the development of small molecules that can be used to fight infection of *Bacillus anthracis*, the microbe that is the cause of anthrax. Thus, the need remains for a more detailed description of the mechanism by which CaM activates EF.

The structures of EF alone, without substrate, or of EF-CaM complex without substrate has not been discovered to date. Such structures are beneficial for the discovery of small molecules that inhibits the activation of EF by CaM. Thus, the

need remains for detailed descriptions of the EF structure without substrate and the EF-CaM complex without substrate.

The inventors have overcome the deficiencies in the prior art by elucidating the molecular structures of (1) EF without CaM or substrate and (2) the structure of EF with CaM. X-ray crystallography images of both structures have been determined and are disclosed by the inventors. A detailed description of the mechanism by which CaM activates EF is disclosed. Also, methods of using diagnostic assays to discover small molecules that can modulate EF activation by CaM are also disclosed.

The ability to inhibit the infection of a bacteria that secretes an adenylyl cyclase exotoxin is significant in that a number of bacterial infections are associated with an increase in cAMP levels in the host by secreting an adenylyl cyclase exotoxin, including; *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*. Any one of these bacterial infections could potentially be treated by inhibiting the activation of the secreted adenylyl cyclase exotoxin.

The findings of the inventors permit the development of novel assay methods for the identification of inhibitors of the activation of secreted adenylyl cyclase exotoxins.

II. Screening Assays

One important aspect of the invention concerns assays for screening for potential new inhibitors of the activation of secreted adenylyl cyclase exotoxins. The assays may be carried out at the protein or nucleic acid level. Such assays may find use in diagnostic applications for directing the treatment of a patient infected with *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis* and similarly, the assays may provide insight as to the relative efficacy of a given inhibitor of the activation of a secreted adenylyl cyclase exotoxin.

The invention provides methods for screening for novel inhibitors of the activation of adenylyl cyclase exotoxins. Such an inhibitor could affect the chemical modification of a molecule in the activation of adenylyl cyclase exotoxins, such as the inhibition of ATP from binding the catalytic site of the adenylyl cyclase exotoxin. In screening assays for polypeptide activity, the candidate substance may first be screened for basic biochemical activity—e.g., binding to a target molecule and then tested for its ability to regulate expression, at the cellular, tissue or whole animal level.

1. Drug Discovery by Structural Based Inhibitor Discovery

Molecular docking can be used to screen compound databases for novel ligands that complement the structure of a binding site (Shoichet et al., 1999; Lorber et al., 2002; Su et al., 2001; Shoichet et al., 2002). The chemical libraries with the known structures can be the compounds from the commercial available sources (i.e. Sigma-Aldrich, MayBridge) or those built by different chemists in the academic institutes or in the biotech or pharmaceutical companies. For example, Molecular Docking has been used to discover novel ligands of lysozyme, inhibitors of β -lactamase and Protein Tyrosine Phosphatase 1B (Powers and Shoichet, 2002; Doman et al., 2002; Wei et al., 2002). Based on the catalytic site of the EF/CaM model, one can define a set of spheres that describe the surface of the CaM binding and catalytic sites. After searching over the compounds from different chemical libraries, the top 500 compounds that may interact with the EF binding site can be modeled more extensively. After manually modeling the interaction between some of these compounds and EF using a molecular graphics program (MIDAS) and checking for commercial availability, initial candidate com-

pounds can be used to screen the compounds that can block adenylyl cyclase activity either by the enzymatic assays (in vitro or in vivo) or by cell-based assays. Concentration-response curves can be generated to determine the IC_{50} value which will provide an estimate of the affinity of a given inhibitor to EF. Those compounds with μ M affinity can be refined by iterative chemical synthesis, testing based on enzymatic activity, and structure determination of EF/CaM/inhibitor complex.

This same technique can also be used for lead optimization. The original hit (such as adenosine or ATP analogs) can be synthesized based on the structures of EF/CaM/ATP complex. Such analogs can be examined for their abilities to inhibit adenylyl cyclase activity of edema factor either by the enzymatic assays (in vitro or in vivo or by cell-based assays). The analysis of structure-activity relationship (SAR) will provide valuable information for chemists to further synthesize the analogs to improve the affinity of lead compounds.

2. Assay Formats to screen for Inhibitors

In certain embodiments, the present invention provides methods for screening and identifying an agent that inhibits the activation of an adenylyl cyclase exotoxin, for example, that stops or decreases EF's adenylyl cyclase activity. Compounds that inhibit the exotoxin's adenylyl cyclase activity can effectively block the increased levels of cAMP in the host cell, thus limiting the negative effects of *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis* on the host cell. This is typically achieved by obtaining the target amino acid site on the adenylyl cyclase exotoxin or the exotoxin/CaM complex, and contacting the amino acid site with candidate agents followed by assays for any change in activity.

Candidate compounds can include fragments or parts of naturally-occurring compounds or may be only found as active combinations of known compounds which are otherwise inactive. In one embodiment, the candidate compounds are small molecules. Alternatively, it is proposed that compounds isolated from natural sources, such as animals, bacteria, fungi, plant sources, including leaves and bark, and marine samples may be assayed as candidates for the presence of potentially useful pharmaceutical agents. It will be understood that the pharmaceutical agents to be screened could also be derived or synthesized from chemical compositions or man-made compounds.

a. In Vitro Assays

The present embodiment of this invention contemplates the use of a method for screening and identifying an agent that inhibits the activation of adenylyl cyclase exotoxins. A quick, inexpensive and easy assay to run is a binding assay. Binding of a molecule to a target may, in and of itself, be inhibitory, due to steric, allosteric or charge-charge interactions. This can be performed in solution or on a solid phase and can be utilized as a first round screen to rapidly eliminate certain compounds before moving into more sophisticated screening assays. The target may be either free in solution, fixed to a support, expressed in or on the surface of a cell. Examples of supports include nitrocellulose, a column or a gel. Either the target or the compound may be labeled, thereby permitting determining of binding. In another embodiment, the assay may measure the enhancement of binding of a target to a natural or artificial substrate or binding partner. Usually, the target will be the labeled species, decreasing the chance that the labeling will interfere with the binding moiety's function. One may measure the amount of free label versus bound label to determine binding or inhibition of binding.

A technique for high throughput screening of compounds is described in WO 84/03564, the disclosure of which is incorporated herein by reference. In high throughput screening, large numbers of candidate inhibitory test compounds, which may be small molecules, natural substrates and ligands, or may be fragments or structural or functional mimetics thereof, are synthesized on a solid substrate, such as plastic pins or some other surface. Alternatively, purified target molecules can be coated directly onto plates or supports for use in drug screening techniques. Also, fusion proteins containing a reactive region (preferably a terminal region) may be used to link an active region of an enzyme to a solid phase, or support. The test compounds are reacted with the target molecule, and bound test compound is detected by various methods (see, e.g., Coligan et al., Current Protocols in Immunology 1(2): Chapter 5 (1991)).

Examples of small molecules that may be screened include, but are not limited to, small organic molecules, peptides or peptide-like molecules, nucleic acids, polypeptides, peptidomimetics, carbohydrates, lipids or other organic (carbon-containing) or inorganic molecules. Many pharmaceutical companies have extensive libraries of chemical and/or biological mixtures, often fungal, bacterial, or algal extracts, which can be screened with any of the assays of the invention to identify compounds that inhibit the activation of adenylyl cyclase exotoxins. Further, in drug discovery, for example, proteins have been fused with antibody Fc portions for the purpose of high-throughput screening assays to identify potential modulators of new polypeptide targets. See, D. Bennett et al., Journal of Molecular Recognition, 8: 52-58 (1995) and K. Johanson et al., The Journal of Biological Chemistry, 270, (16): 9459-9471 (1995).

b. In Vivo Assays

In vivo assays involve the use of various animal models, including transgenic animals that have been engineered to have specific defects, or carry markers that can be used to measure the ability of a candidate substance to reach and effect different cells within the organism. Due to their size, ease of handling, and information on their physiology and genetic make-up, mice are a preferred embodiment, especially for transgenics. However, other animals are suitable as well, including rats, rabbits, hamsters, guinea pigs, gerbils, woodchucks, cats, dogs, sheep, goats, pigs, cows, horses and monkeys (including chimps, gibbons and baboons). Assays for modulators may be conducted using an animal model derived from any of these species.

In such assays, one or more candidate substances are administered to an animal, and the ability of the candidate substance(s) to alter one or more characteristics, as compared to a similar animal not treated with the candidate substance(s), identifies a modulator. The characteristics may be any of those discussed above with regard to the function of a particular compound (e.g., enzyme, receptor, hormone) or cell (e.g., growth, tumorigenicity, survival), or instead a broader indication such as behavior, anemia, immune response, etc.

The present invention provides methods of screening for a candidate substance that can inhibit the activation of adenylyl cyclase exotoxins secreted by *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*. In these embodiments, the present invention is directed to a method for determining the ability of a candidate substance to inhibit the activation of the adenylyl cyclase exotoxins secreted by *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*, generally including the steps of: administering a candidate substance to

the animal; and determining the ability of the candidate substance to reduce one or more characteristics of the infection of *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*

Treatment of these animals with test compounds will involve the administration of the compound, in an appropriate form, to the animal. Administration will be by any route that could be utilized for clinical or non-clinical purposes, including but not limited to oral, nasal, buccal, or even topical. Alternatively, administration may be by intratracheal instillation, bronchial instillation, intradermal, subcutaneous, intramuscular, intraperitoneal or intravenous injection. Specifically contemplated routes are systemic intravenous injection, regional administration via blood or lymph supply, or directly to an affected site.

Determining the effectiveness of a compound in vivo may involve a variety of different criteria. Also, measuring toxicity and dose response can be performed in animals in a more meaningful fashion than in in vitro or in cyto assays.

c. In Cyto Assays

The present invention also contemplates the screening of compounds for their ability to inhibit the activation of adenylyl cyclase exotoxins secreted by *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*. Various cell lines can be utilized for such screening assays, including cells specifically engineered for this purpose. Depending on the assay, culture may be required. The cell is examined using any of a number of different assays for screening for adenylyl cyclase activation in the cells.

d. Arrays

Hi-throughput assays, for example, arrays comprising a plurality of ligands arranged on a solid support, represent an important diagnostic tool provided by the invention. The use of arrays involves the placement and binding of nucleic acids, or another type of ligand having affinity for a molecule in a test sample, to known locations, termed sectors, on a solid support.

Arrays can be used, through hybridization of a test sample to the array, to determine the presence or absence of a given molecule in the sample. By including any additional other target nucleic acids or other types of ligands, potentially thousands of target molecules can be simultaneously screened for in a test sample. Many different methods for preparation of arrays comprising target substances arranged on solid supports are known to those of skill in the art and could be used in accordance with the invention. Specific methods for preparation of such arrays are disclosed in, for example, Affinity Techniques, Enzyme Purification: Part B, Meth. Enz. 34 (ed. W. B. Jakoby and M. Wilchek, Acad. Press, N.Y. (1974) and Immobilized Biochemicals and Affinity Chromatography, Adv. Exp. Med. Biol. 42 (ed. R. Dunlap, Plenum Press, N.F. 1974), each specifically incorporated herein by reference in its entirety). Examples of other techniques which have been described for the attachment of test materials to arrays include the use of successive application of multiple layers of biotin, avidin, and extenders (U.S. Pat. No. 4,282,287, specifically incorporated herein by reference in its entirety); methods employing a photochemically active reagent and a coupling agent which attaches the photoreagent to the substrate (U.S. Pat. No. 4,542,102, specifically incorporated herein by reference in its entirety); use of polyacrylamide supports on which are immobilized oligonucleotides (PCT Patent Publication No. 90/07582, specifically incorporated herein by reference in its entirety); use of solid supports on which oligonucleotides are immobilized via a 5'-dithio linkage (PCT Patent Publication No. 91/00868, specifically

incorporated herein by reference in its entirety); and through use of a photoactivatable derivative of biotin as the agent for immobilizing a biological polymer of interest onto a solid support (see U.S. Pat. No. 5,252,743; and PCT Patent Publication No. 91/07087 to Barrett et al., each specifically incorporated herein by reference in its entirety). In the case of a solid support made of nitrocellulose or the like, standard techniques for UV-crosslinking may be of particular utility (Sambrook et al., 1989).

The solid support surface upon which an array is produced in accordance with the invention may potentially be any suitable substance. Examples of materials which may be used include polymers, plastics, resins, polysaccharides, silica or silica-based materials, carbon, metals, inorganic glasses, membranes, etc. It may also be advantageous to use a surface which is optically transparent, such as flat glass or a thin layer of single-crystal silicon. Contemplated as being especially useful are nylon filters, such as Hybond N+ (Amersham Corporation, Amersham, UK). Surfaces on the solid substrate will usually, though not always, be composed of the same material as the substrate, and the surface may further contain reactive groups, which could be carboxyl, amino, hydroxyl, or the like.

It is contemplated that one may wish to use a solid support surface which is provided with a layer of crosslinking groups (U.S. Pat. No. 5,412,087, specifically incorporated herein by reference in its entirety). Crosslinking groups could be selected from any suitable class of compounds, for example, aryl acetylenes, ethylene glycol oligomers containing 2 to 10 monomer units, diamines, diacids, amino acids, or combinations thereof. Crosslinking groups can be attached to the surface by a variety of methods that will be readily apparent to one of skill in the art. For example, crosslinking groups may be attached to the surface by siloxane bonds formed via reactions of crosslinking groups bearing trichlorosilyl or trisalkoxy groups with hydroxyl groups on the surface of the substrate. The crosslinking groups can be attached in an ordered array, i.e., as parts of the head groups in a polymerized Langmuir Blodgett film. The linking groups may be attached by a variety of methods that are readily apparent to one skilled in the art, for instance, by esterification or amidation reactions of an activated ester of the linking group with a reactive hydroxyl or amine on the free end of the crosslinking group.

A significant benefit of the arrays of the invention is that they may be used to simultaneously screen for inhibitors of the activation of secreted adenylyl cyclase exotoxins. Use of the arrays generally will comprise, in a first step, contacting the array with a test sample. Generally the test sample will be labeled to facilitate detection of hybridizing test samples. By detection of test samples having affinity for bound target nucleic acids or other ligands, the identity of the target molecule will be known.

Following contacting with the test sample, the solid support surface is then generally washed free of unbound test sample, and the signal corresponding to the probe label is identified for those regions on the surface where the test sample has high affinity. Suitable labels for the test sample include, but are not limited to, radiolabels, chromophores, fluorophores, chemiluminescent moieties, antigens and transition metals. In the case of a fluorescent label, detection can be accomplished with a charge-coupled device (CCD), fluorescence microscopy, or laser scanning (U.S. Pat. No. 5,445,934, specifically incorporated herein by reference in its entirety). When autoradiography is the detection method used, the marker is a radioactive label, such as ^{32}P , and the surface is exposed to X-ray film, which is developed and read

out on a scanner or, alternatively, simply scored manually. With radiolabeled probes, exposure time will typically range from one hour to several days. Fluorescence detection using a fluorophore label, such as fluorescein, attached to the ligand will usually require shorter exposure times. Alternatively, the presence of a bound probe may be detected using a variety of other techniques, such as an assay with a labeled enzyme, antibody, or the like. Detection also may, in the case of nucleic acids, alternatively be carried out using PCR. In this instance, PCR detection may be carried out in situ on the slide. In this case one may wish to utilize one or more labeled nucleotides in the PCR mix to produce a detectable signal. Other techniques using various marker systems for detecting bound ligand will also be readily apparent to those skilled in the art.

III. Immunological Detection

1. Immunoassays

Immunoassays may find use with the invention in certain prognostic/diagnostic applications that comprise assaying for the presence of the adenylyl cyclase exotoxin and/or the exotoxin-CaM molecule. As indicated above, such immunoassays specifically include the use of high-throughput techniques including use of arrays. The steps of various useful immunodetection methods have been described in the scientific literature, such as, e.g., Nakamura et al. (1987; incorporated herein by reference). Immunoassays, in their most simple and direct sense, are binding assays. Certain preferred immunoassays are the various types of enzyme linked immunosorbent assays (ELISAs), radioimmunoassays (RIA) and immunobead capture assay. Immunohistochemical detection using tissue sections also is particularly useful. However, it will be readily appreciated that detection is not limited to such techniques, and Western blotting, dot blotting, FACS analyses, and the like also may be used in connection with the present invention.

In general, immunobinding methods include obtaining a sample suspected of containing a protein, peptide or antibody, and contacting the sample with an antibody or protein or peptide in accordance with the present invention, as the case may be, under conditions effective to allow the formation of immunocomplexes.

The immunobinding methods of this invention include methods for detecting or quantifying the amount of a reactive component in a sample, which methods require the detection or quantitation of any immune complexes formed during the binding process. Here, one would obtain a sample containing a target protein or peptide, and contact the sample with an antibody, as the case may be, and then detect or quantify the amount of immune complexes formed under the specific conditions.

Contacting the chosen biological sample with the protein, peptide or antibody under conditions effective and for a period of time sufficient to allow the formation of immune complexes (primary immune complexes) is generally a matter of simply adding the composition to the sample and incubating the mixture for a period of time long enough for the antibodies to form immune complexes with, i.e., to bind to, any antigens present, such as the EF protein or the EF-CaM molecule as seen in *Bacillus anthracis*. After this time, the sample-antibody composition, such as a tissue section, ELISA plate, dot blot or Western blot, will generally be washed to remove any non-specifically bound antibody species, allowing only those antibodies specifically bound within the primary immune complexes to be detected.

In general, the detection of immunocomplex formation is well known in the art and may be achieved through the application of numerous approaches. These methods are generally

based upon the detection of a label or marker, such as any radioactive, fluorescent, biological or enzymatic tags or labels of standard use in the art. U.S. Patents concerning the use of such labels include U.S. Pat. Nos. 3,817,837; 3,850,752; 3,939,350; 3,996,345; 4,277,437; 4,275,149 and 4,366,241, each incorporated herein by reference.

The immunodetection methods of the present invention have evident utility in the diagnosis anthrax. Here, a biological or clinical sample suspected of containing either the encoded protein or peptide or corresponding antibody is used. However, these embodiments also have applications to non-clinical samples, such as in the titering of antigen or antibody samples, in the selection of hybridomas, and the like.

IV. Therapeutic Application of the Invention

The current invention provides methods and compositions for the inhibition of the activation of adeneyl cyclase exotoxins secreted by *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*. The invention therefore provides therapies to treat these bacterial infections, for example, by administering a pharmaceutical composition comprising an inhibitor of the activation of the adenyl cyclase exotoxin secreted by *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis*. Administration may be by any route that could be utilized for clinical or non-clinical purposes, including but not limited to oral, nasal, buccal, or even topical. Alternatively, administration may be by intratracheal instillation, bronchial instillation, intradermal, subcutaneous, intramuscular, intraperitoneal or intravenous injection.

V. Pharmaceutical Compositions and Dosages

Pharmaceutical compositions of the present invention comprise an effective amount of one or more inhibitors of the activation of adeneyl cyclase exotoxins secreted by *Bacillus anthracis*, *Bordetella pertussis*, *Pseudomonas aeruginosa*, and/or *Yersinia pestis* or additional agent dissolved or dispersed in a pharmaceutically acceptable carrier. The phrases "pharmaceutical or pharmacologically acceptable" refers to molecular entities and compositions that do not produce an adverse, allergic or other untoward reaction when administered to an animal, such as, for example, a human, as appropriate. The preparation of a pharmaceutical composition that contains at least one inhibitor of adenyl cyclase activity or additional active ingredient will be known to those of skill in the art in light of the present disclosure, as exemplified by Remington's Pharmaceutical Sciences, 18th Ed. Mack Printing Company, 1990, incorporated herein by reference. Moreover, for animal (e.g., human) administration, it will be understood that preparations should meet sterility, pyrogenicity, general safety and purity standards as required by FDA Office of Biological Standards.

As used herein, "pharmaceutically acceptable carrier" includes any and all solvents, dispersion media, coatings, surfactants, antioxidants, preservatives (e.g., antibacterial agents, antifungal agents), isotonic agents, absorption delaying agents, salts, preservatives, drugs, drug stabilizers, gels, binders, excipients, disintegration agents, lubricants, sweetening agents, flavoring agents, dyes, such like materials and combinations thereof, as would be known to one of ordinary skill in the art (Remington's, 1990). Except insofar as any conventional carrier is incompatible with the active ingredient, its use in the therapeutic or pharmaceutical compositions is contemplated.

The inhibitors of the activation of adeneyl cyclase exotoxins may comprise different types of carriers depending on whether it is to be administered in solid, liquid or aerosol form, and whether it need to be sterile for such routes of

administration as injection. The present invention can be administered intravenously, intradermally, intraarterially, intraperitoneally, intralesionally, intracranially, intraarticularly, intraprostatically, intrapleurally, intratracheally, intranasally, intravitreally, intravaginally, intrarectally, topically, intratumorally, intramuscularly, intraperitoneally, subcutaneously, subconjunctival, intravesicularly, mucosally, intrapericardially, intraumbilically, intraocularly, orally, topically, locally, inhalation (e.g. aerosol inhalation), injection, infusion, continuous infusion, localized perfusion bathing target cells directly, via a catheter, via a lavage, in cremes, in lipid compositions (e.g., liposomes), or by other method or any combination of the forgoing as would be known to one of ordinary skill in the art (Remington's, 1990).

The actual dosage amount of a composition of the present invention administered to an animal patient can be determined by physical and physiological factors such as body weight, severity of condition, the type of disease being treated, previous or concurrent therapeutic interventions, idiosyncrasy of the patient and on the route of administration. The practitioner responsible for administration will, in any event, determine the concentration of active ingredient(s) in a composition and appropriate dose(s) for the individual subject.

In certain embodiments, pharmaceutical compositions may comprise, for example, at least about 0.1% of an active compound. In other embodiments, the an active compound may comprise between about 2% to about 75% of the weight of the unit, or between about 25% to about 60%, for example, and any range derivable therein. In other non-limiting examples, a dose may also comprise from about 1 microgram/kg/body weight, about 5 microgram/kg/body weight, about 10 microgram/kg/body weight, about 50 microgram/kg/body weight, about 100 microgram/kg/body weight, about 200 microgram/kg/body weight, about 350 microgram/kg/body weight, about 500 microgram/kg/body weight, about 1 milligram/kg/body weight, about 5 milligram/kg/body weight, about 10 milligram/kg/body weight, about 50 milligram/kg/body weight, about 100 milligram/kg/body weight, about 200 milligram/kg/body weight, about 350 milligram/kg/body weight, about 500 milligram/kg/body weight, to about 1000 mg/kg/body weight or more per administration, and any range derivable therein. In non-limiting examples of a derivable range from the numbers listed herein, a range of about 5 mg/kg/body weight to about 100 mg/kg/body weight, about 5 microgram/kg/body weight to about 500 milligram/kg/body weight, etc., can be administered, based on the numbers described above.

In any case, the composition may comprise various antioxidants to retard oxidation of one or more component. Additionally, the prevention of the action of microorganisms can be brought about by preservatives such as various antibacterial and antifungal agents, including but not limited to parabens (e.g., methylparabens, propylparabens), chlorobutanol, phenol, sorbic acid, thimerosal or combinations thereof.

The inhibitors of the activation of adeneyl cyclase exotoxins may be formulated into a composition in a free base, neutral or salt form. Pharmaceutically acceptable salts, include the acid addition salts, e.g., those formed with the free amino groups of a proteinaceous composition, or which are formed with inorganic acids such as for example, hydrochloric or phosphoric acids, or such organic acids as acetic, oxalic, tartaric or mandelic acid. Salts formed with the free carboxyl groups can also be derived from inorganic bases such as for example, sodium, potassium, ammonium, calcium or ferric hydroxides; or such organic bases as isopropylamine, trimethylamine, histidine or procaine.

In embodiments where the composition is in a liquid form, a carrier can be a solvent or dispersion medium comprising but not limited to, water, ethanol, polyol (e.g., glycerol, propylene glycol, liquid polyethylene glycol, etc), lipids (e.g., triglycerides, vegetable oils, liposomes) and combinations thereof. The proper fluidity can be maintained, for example, by the use of a coating, such as lecithin; by the maintenance of the required particle size by dispersion in carriers such as, for example liquid polyol or lipids; by the use of surfactants such as, for example hydroxypropylcellulose; or combinations thereof such methods. In many cases, it will be preferable to include isotonic agents, such as, for example, sugars, sodium chloride or combinations thereof.

In other embodiments, one may use eye drops, nasal solutions or sprays, aerosols or inhalants in the present invention. Such compositions are generally designed to be compatible with the target tissue type. In a non-limiting example, nasal solutions are usually aqueous solutions designed to be administered to the nasal passages in drops or sprays. Nasal solutions are prepared so that they are similar in many respects to nasal secretions, so that normal ciliary action is maintained. Thus, in preferred embodiments, the aqueous nasal solutions usually are isotonic or slightly buffered to maintain a pH of about 5.5 to about 6.5. In addition, antimicrobial preservatives, similar to those used in ophthalmic preparations, drugs, or appropriate drug stabilizers, if required, may be included in the formulation. For example, various commercial nasal preparations are known and include drugs such as antibiotics or antihistamines.

In certain embodiments, the inhibitors of the activation of adenyl cyclase exotoxins are prepared for administration by such routes as oral ingestion. In these embodiments, the solid composition may comprise, for example, solutions, suspensions, emulsions, tablets, pills, capsules (e.g., hard or soft shelled gelatin capsules), sustained release formulations, buccal compositions, troches, elixirs, suspensions, syrups, wafers, or combinations thereof. Oral compositions may be incorporated directly with the food of the diet. Preferred carriers for oral administration comprise inert diluents, assimilable edible carriers or combinations thereof. In other aspects of the invention, the oral composition may be prepared as a syrup or elixir. A syrup or elixir, and may comprise, for example, at least one active agent, a sweetening agent, a preservative, a flavoring agent, a dye, a preservative, or combinations thereof.

In certain preferred embodiments an oral composition may comprise one or more binders, excipients, disintegration agents, lubricants, flavoring agents, and combinations thereof. In certain embodiments, a composition may comprise one or more of the following: a binder, such as, for example, gum tragacanth, acacia, cornstarch, gelatin or combinations thereof, an excipient, such as, for example, dicalcium phosphate, mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate or combinations thereof; a disintegrating agent, such as, for example, corn starch, potato starch, alginic acid or combinations thereof; a lubricant, such as, for example, magnesium stearate; a sweetening agent, such as, for example, sucrose, lactose, saccharin or combinations thereof; a flavoring agent, such as, for example peppermint, oil of wintergreen, cherry flavoring, orange flavoring, etc.; or combinations thereof the foregoing. When the dosage unit form is a capsule, it may contain, in addition to materials of the above type, carriers such as a liquid carrier. Various other materials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets, pills, or capsules may be coated with shellac, sugar or both.

Additional formulations which are suitable for other modes of administration include suppositories. Suppositories are solid dosage forms of various weights and shapes, usually medicated, for insertion into the rectum, vagina or urethra. After insertion, suppositories soften, melt or dissolve in the cavity fluids. In general, for suppositories, traditional carriers may include, for example, polyalkylene glycols, triglycerides or combinations thereof. In certain embodiments, suppositories may be formed from mixtures containing, for example, the active ingredient in the range of about 0.5% to about 10%, and preferably about 1% to about 2%.

Sterile injectable solutions are prepared by incorporating the active compounds in the required amount in the appropriate solvent with various of the other ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the various sterilized active ingredients into a sterile vehicle which contains the basic dispersion medium and/or the other ingredients. In the case of sterile powders for the preparation of sterile injectable solutions, suspensions or emulsion, the preferred methods of preparation are vacuum-drying or freeze-drying techniques which yield a powder of the active ingredient plus any additional desired ingredient from a previously sterile-filtered liquid medium thereof. The liquid medium should be suitably buffered if necessary and the liquid diluent first rendered isotonic prior to injection with sufficient saline or glucose. The preparation of highly concentrated compositions for direct injection is also contemplated, where the use of DMSO as solvent is envisioned to result in extremely rapid penetration, delivering high concentrations of the active agents to a small area.

The composition must be stable under the conditions of manufacture and storage, and preserved against the contaminating action of microorganisms, such as bacteria and fungi. It will be appreciated that exotoxin contamination should be kept minimally at a safe level, for example, less than 0.5 ng/mg protein.

In particular embodiments, prolonged absorption of an injectable composition can be brought about by the use in the compositions of agents delaying absorption, such as, for example, aluminum monostearate, gelatin or combinations thereof.

EXAMPLES

Example 1

General Description of the EF structure with and without CaM

The structure of EF-CaM at 2.75 Å resolution was solved using selenomethionine multiple wavelength anomalous diffraction (MAD) in conjunction with conventional heavy atom methods (Drum et al., 2001) (Table 1). The structure of EF without CaM or substrate at 2.6 Å resolution was solved by molecular replacement using the catalytic core domains of EF-CaM/3-d'ATP as the model. Crystals of the EF-CaM complex in the absence of the nucleotide substrate were isomorphous with those of the 3'-dATP-bound CaM complex. The R-factors for EF alone, EF-CaM-3'dATP, and EF-CaM are 22.8%($R_{free}=27.6\%$), 21.5%(28.6%), and 27.8%(31.5%), respectively.

TABLE 1

Crystallographic and refinement statistics			
A. Crystallographic data			
Crystal	EF3-CH ₆ -CaM-3'dATP	H ₆ -EF3	EF3-CH ₆ -CaM
Space group	I222	P2 ₁ 2 ₁ 2	I222

Bond length (Å)	0.005	0.011	0.011
Bond angle (degree)	1.8	1.55	1.6

The structure of EF alone differs significantly from that of EF-CaM. There are, however, essentially no differences between the structures of EF-CaM with and without nucleotide (FIG. 1A and FIG. 1B). Thus, the differences between EF alone and EF-CaM are almost entirely CaM-induced. The catalytic portion of EF is composed of three globular domains (FIG. 1A, FIG. 1B, and FIG. 2). The active site lies at the interface of two domains, C_A (a.a. 294-349 and 490-622) and C_B (a.a. 350-489), which together constitute the catalytic core. A third, helical domain (residues 660-800), is connected to C_A by a linker (residues 623-659). In the structure of EF alone, the interface between the helical domain and the remainder of the protein buries 16 hydrophobic residues and 3600 Å² of surface area. None of these interactions are preserved in the EF-CaM complex, however, since CaM inserts itself between C_A and the helical domain. In doing so, CaM occupies much of the same volume occupied by the helical domain in the structure of EF-alone. To accommodate CaM, the helical domain, acting as a unit, moves 15 Å and rotates 30°, such that C_A, the linker, and the helical domain now form a large clamp which almost completely encircles the activator. There are no contacts between C_A and the helical domain in the EF-CaM structures, but residues from these domains approaching from either side of CaM come within 5.6 Å of one another at the tip of the clamp (FIG. 3A, and FIG. 3B). The CaM interface buries 2950 Å² and 2912 Å² of solvent accessible surface area on EF and CaM, respectively.

In addition to the helical domain movement, three regions designated as switch A, B and C undergo large conformational changes in response to CaM binding (FIG. 1A, FIG. 1B, FIG. 4A, FIG. 4B, and FIG. 4C). Switch A and C are the predominant regions that interface with the helical domain in the EF-alone structure, thus they have a large movement to accommodate the insertion of CaM (FIG. 2). Switch A (a.a. 502-551) includes residues that bind CaM and nucleotide. In the EF-alone structure, this loop is nestled on the side of domain C_A and its tip is 20 Å away from its active state position. Switch C (a.a. 630-659) is composed of residues from the linker that connects C_A to the helical domain. This region undergoes the largest structural change within EF. The tip of the Switch C loop swings 33 Å from its position near the active site in EF-CaM to the opposite side of the enzyme in EF alone. Within switch C, residues 642-652 are converted from

two β-strands and a connecting loop to a helix in the EF-CaM structure (residues 648-653). Switch B (a.a. 578-591), which makes several specific contacts with the substrate in EF-CaM, becomes disordered when CaM is not present. This disorder cannot be attributed to the lack of substrate in the EF-alone structure since these residues are clearly visible in the structure of substrate-free EF-CaM (FIG. 4B). Switch B also makes extensive contacts with switch C in the EF-CaM complex. Outside of the helical domain and the three defined switches, the remaining residues are relatively unchanged.

Example 2

Geometry of the Active Site of EF-CaM Complex

3'dATP, a non-cyclizable substrate analog, is clearly visible in simulated annealing omit maps of the EF-CaM-3'dATP structure (supplemental material). Residues from six segments of the protein form the substrate-binding pocket (FIG. 5A). These residues form a network of hydrogen bonds and ionic interactions, which completely encircle the triphosphate and ribose moieties, forming an enclosed cavity with openings at both ends (FIG. 5A). The most notable phosphate interactions are made by K346, which contacts oxygens from all three phosphates; R329, which interacts with the β-phosphate; and K372 and S354, which interact with the γ-phosphate (FIG. 5A). F586 and L348 lie above and below the plane of the ribose, and the side chain of N583 forms a hydrogen bond with O4' of the ribose ring. The adenosine ring, though solvent accessible, contacts the backbone of D582 and N583, and the N6 nitrogen is within hydrogen bonding distance of the main chain carbonyls of T579 and T548. Mutational analysis of many of these residues supports their importance in catalysis (table 2) (Drum et al., 2000).

^aThe adenyl cyclase assay was performed with EF, K353R, E588A, D590A, L523A, K525A, Q526A, V529A (5 ng), K353A, H577N, H577D, N583A, N583Q, N583H, N639A, D647A (50 ng), and H577N, K346R (15 μg) at 30° C. for 10 min in the presence of 5 mM ATP, 10 mM MgCl₂ and 0.05 mM CaCl₂. EC_{50,CaM} was determined using CaM concentration ranging from 0.01 to 1000 nM in 3.1 or 10 fold increments and the results were fit to a simple rectangular hyperbola. K_{M,ATP} was determined using ATP concentrations ranging from 0.06 to 2 mM in 2 fold increments and the results were fit in the same way. These data are representative of at least two experiments. These data are representative of at least two experiments.

At the base of the cleft formed by domains C_A and C_B, a single metal interacts with the oxygens of the alpha and beta phosphates of 3'-deoxy ATP. This metal is coordinated by two conserved aspartates, D491 and D493. Mutation of either

aspartic acid in EF and its homologs CyaA, and ExoY (exotoxins from *Bordetella pertussis* and *Pseudomonas aeruginosa*, respectively) results in catalytic inactivation of the enzyme (FIG. 2) (Yahr et al., 1998; Drum et al., 2000; Glaser et al., 1991). Based on the strength of the electron density and the anomalous scattering signal, we believe the metal present in our highest resolution data set is Yb^{2+} , an additive used to improve crystal quality. This Yb^{2+} is at the presumed position of the catalytic Mg^{2+} , which interacts with the α - and β -phosphates of the substrate. Though Yb and Mg ions were both present in the crystallization mixture, no metal ion was found in the catalytic site of EF-CaM in the absence of ATP analog (FIG. 4B). This suggests that the presence of substrate may be required for binding of the catalytic metal ion. However, based on the anomalous scattering signal, a Ni^{2+} ion is coordinated by D491 and D493 in the catalytic site of the EF alone structure (FIG. 4A). Since diffracting crystals of EF alone were only obtained at high NiSO_4 concentration (220-280 mM), the physiological relevance of this metal ion found in the catalytic site remains unclear.

H351 lies on the opposite side of the ribose from the metal and is well positioned to interact with the reactive 3'OH when the ribose is in the 3'-endo conformation observed in the crystal (FIG. 5A). The homologous histidine in CyaA, H63, has been shown to act as a catalytic base (Munier et al., 1992). Though the 3' hydroxyl is absent from the nucleotide analog used in this study, the expected position of this atom is generally consistent with that required for in-line nucleophilic attack on the α -phosphate. In this reaction scheme, the metal, along with K346, would serve to activate the α -phosphate and stabilize the developing charge on the oxygen bridging the α - and β -phosphates (FIG. 5B). This catalytic mechanism differs from that proposed for mammalian adenylyl cyclases (mAC), which are thought to utilize a two-metal-ion catalysis. Whereas H577 appears to be positioned such that it could coordinate a second metal ion in conjunction with D493, mutational analysis argues against such a role (Table 2). H577N has 250-fold higher catalytic activity than H577D, a mutation that would favor the binding of second metal ion.

Example 3

Comparison of EF and Mammalian Adenylyl Cyclase

Four genetically unrelated groups catalogue all known adenylyl cyclases. While the catalytic core structures of mAC and ESAG from *Trypanosoma brucei* (class III, the family of adenylyl cyclases from bacteria to mammals (Tang and Hurley, 1998) have been determined crystallographically (Tesmer et al., 1997; Bieger and Essen, 2001), EF represents the first member of the adenylyl cyclase toxin family (class II) to be structurally characterized. Comparison of these two classes reveals no obvious structural homology (FIG. 5D). Whereas the catalytic portion of the mammalian enzymes is composed of two similarly folded domains, C1a and C2a, with rough two-fold symmetry; EF, which functions as a soluble monomer, has no such symmetry. Superimposing the ATPaS nucleotide from mAC with the 3'dATP nucleotide seen in EF-CaM reveals that despite a lack of overall structural homology, there are residue-level similarities in substrate binding and catalysis between these two enzyme families (FIG. 5A and FIG. 5C) (Tesmer et al., 1997). Both enzymes have an asparagine (N583 of EF and N1025 of mAC) that forms a hydrogen bond to the O4' of the ribose ring and could serve to position the ribose. Both enzymes also have a cluster of positively charged residues (R329, K346, K372 of EF and

R1029, K1065, and R484 of mAC), which could serve to stabilize the pentavalent transition state formed during catalysis. In addition, both enzymes contain a catalytically required metal ion, which is held in position by two aspartates (D491 and D493 of EF and D396 and D440 of mAC). These similarities do not extend beyond the immediate vicinity of the catalytic center, with structural divergence seen even in the contacts stabilizing the adenine rings (FIG. 5A and FIG. 5C).

The mechanism whereby EF and mAC generate the attacking 3' O— is also 10 different (FIG. 5A and FIG. 5C). In EF, H351 appears to serve as a catalytic base, removing the proton from the 3'OH. mACs and their relatives do not have a conserved histidine in their catalytic site, and are thought to use a second metal ion for this purpose (Tesmer et al., 1999). mACs have structural homology to the catalytic "palm domains" of the oligonucleotide polymerase family, a family known to use two-metal-ion catalysis (Tesmer et al., 1999). Supporting the assertion that mACs work like polymerases, a second metal ion (ion A), adjacent to the first (ion B), has been observed in the structure of zinc-complexed mAC (Tesmer et al., 1999). Substitution of the metal at site A with a histidine for deprotonation is not unprecedented. Most restriction endonucleases (which catalyze destruction rather than formation of a phosphodiester bond) use two-metal-ion catalysis, however two homing endonucleases, I-PpoI and Serratia nuclease, are known to have a histidine for deprotonation instead of a site A metal (Galburt et al., 1999; Miller and Krause, 1999).

The ribose in the structure of mAC/ATPocS is oriented such that the 3'OH is too far for effective deprotonation from metal ion A (5.3 Å) (FIG. 5C) (Tesmer et al., 1999). As the ribose in the mAC structure is oriented similarly to that seen in EF, an alternative mechanism of catalysis can be proposed. In the structure of mAC, a well-ordered water molecule, 3 Å from the 3'OH of ATP α S, forms a hydrogen bond with the hydroxyl group of serine 1028 (FIG. 5C). This water molecule is also 3 Å from the amino group of R1029, a conserved residue that is crucial for catalysis (Yan et al., 1997). Were this "water" a hydroxide anion, stabilized by the nearby arginine, it could serve as a base to draw the proton from the 3'OH. Alternatively, R1029, with its amino group is 3.5 Å away from 3'OH, might serve to stabilize 3' O⁻ or act as a catalytic base directly.

Example 4

CaM Binding of EF

CaM adopts an extended conformation when bound to EF. The distance between the two CaM lobes is similar to that observed in the crystal structure of extended, Ca^{2+} -bound calmodulin (Babu et al., 1985). However, the EF interaction causes residues 79-81 of the central helix to unwind, and causes the N-terminal CaM lobe to rotate by 80° with respect to the Ca^{2+} -bound crystal structure (FIG. 1A and FIG. 1B). Unwinding of the CaM central helix is not surprising as this region is flexible in solution and is readily unfolded upon target binding (Lewit-Bentley and Rety, 2000). In the EF-CaM structure, the C-terminal domain of CaM binds two calcium ions and is similar to that seen in previous Ca^{2+} -loaded CaM structures (rmsd 0.62 Å over 61 amino acids) (Babu et al., 1985). Consistent with biochemical data, the N-terminal lobe adopts a calcium-free conformation (rmsd 1.2 Å over 67 amino acids) (Drum et al., 2000; Zhang et al., 1995).

Calcium-binding EF-hand domains undergo a variety of interactions with other proteins (Meng et al., 1998; Huang et

al., 2000). The structure of EF-CaM suggests that CaM can also use an extensive repertoire of conformations and interactions as it regulates its many targets. An intricate network of hydrophobic and hydrophilic contacts appears to be responsible for the tight binding constant between EF and CaM ($K_d=20$ nM) (Drum et al., 2000). Excluding residues with less than 10 \AA^2 of contact area, 63 predominantly hydrophobic and basic EF residues contact 53 residues from CaM (FIG. 2). These contacts are divided among two segments of the EF sequence; residues **501-540**, which are part of domain C_A , and residues **616-798**, which correspond to switch C and the helical domain. The first segment was previously identified as a CaM binding domain, and this region has also been identified in CyaA (Munier et al., 1995). This first segment interacts with CaM helices IV, V, and VI, and, as discussed below, part of this segment is structurally similar to other CaM-target interactions (FIG. 6A). The latter segment consists of multiple CaM/effector binding surfaces, and the interaction of this part of EF with CaM is consistent with cross-linking data (Labruyere et al., 1990). Within this latter region, there are three discrete CaM binding segment (residue **615-634**, **647-672**, and **695-721**) to form extensive contacts with three out of four EF-hand domains in CaM (FIG. 2 and FIG. 6A). The EF helices L and M make significant contacts to the first EF hand domain of CaM which appears to stabilize the Ca^{2+} -free conformation observed in the N-terminal CaM lobe.

Example 5

Activation of EF by CaM

The adenylyl cyclase domain of EF is basic, with a calculated pI of 9.0. In the EF alone structure, C_A , the helical domain and switch C form a contiguous, positively charged surface which is likely to be a driving force in attracting the highly negatively charged CaM (pI=3.9). The affinity of the helical domain for the enzymatic core is likely to be a primary energetic obstacle to EF activation. The unusually large binding surface between EF and CaM, however, may serve to generate enough free energy to simultaneously allow high affinity CaM binding and to stabilize the structural rearrangements which activate EF. All four CaM binding regions of EF are partially buried (FIG. 4A, FIG. 4B, FIG. 4C, FIG. 5A, FIG. 5B, FIG. 5C and FIG. 5D). The inventors use alanine-scanning mutagenesis to characterize the order of CaM binding to two of these four regions (FIG. 6A). In the EF-CaM structure, the amino group of K525 within helix H forms a 4.0 \AA salt bridge with the carboxyl group of CaM residue E114 (FIG. 6A). In EF alone structure, K525 is largely exposed. The K525A mutation drastically increases the EC_{50} value (200 fold) with only a small reduction in V_{max} (FIG. 6B and Table 2). The mutations in nearby residues L523, Q526, and V529 result in minimal changes in CaM activation (Table 2). These data indicate that helix H is important for the initial binding of EF to CaM with K525 being a binding hot spot.

Switch C is immediately connected to the helical domain and undergoes the largest conformational change upon CaM binding. Its C-terminal portion (a.a. **646-659**) interacts extensively with helices IV' and VII and the third calcium binding loop of CaM. Most noticeably, the carboxyl group of D647 forms a salt bridge with the guanido group of R90 from CaM (FIG. 6A). In the EF alone structure, D647 is mostly buried and forms a network of hydrogen bonds with the hydroxyl group of S669 and amide groups of P648 and 1649. Thus, the interaction of D647 with CaM is likely to occur after the conformational change of switch C induced by the initial binding of CaM. The mutation of D647 to alanine is consis-

tent with this notion. D647A has a significant reduction in the V_{max} value for CaM activation while its EC_{50} value has little change (FIG. 6B and Table 2).

In the EF alone structure, switch B is disordered, but it becomes highly ordered in the EF-CaM complex (FIG. 4A, FIG. 4B, and FIG. 4C). This transition is most likely due to the extensive contacts between switch B and the N-terminal portion of switch C (aa **631-644**). Noticeably, the amide group of N639 forms hydrogen bonds with the main chain carbonyl of P587. Consequently, the mutation of N639 to alanine results in a 12-fold reduction in the rate of catalysis (FIG. 4C, Table 2).

Switch B (a.a. **579-591**) contains several residues that either bind ATP directly or stabilize the catalytic residues (FIG. 3A and FIG. 3B). The main chain carbonyl of T579 forms hydrogen bonds with N6 of the adenine base, and the amide group of N583 forms a crucial interaction with the ribose. Mutating N583 to alanine causes a 180-fold reduction in catalytic activity (FIG. 4C, Table 2). Substitutions of N583 to other hydrogen-bond forming residues such as glutamine and histidine result in greater than 400 fold reduction, highlighting the importance of the precise stereochemistry of the N583 side chain (FIG. 4C, Table 2). ATP is locked into the catalytic site by a salt bridge formed between the carboxyl group of E588 and the amino group of K353. Mutations of either residue result in a significant reduction in the catalytic activity (FIG. 4C, Table 2). In addition, the carboxyl group of D590 forms a salt bridge with the guanido group of R329, which interacts with the ATP β -phosphate. R329 participates directly in catalysis, and the mutation of D590 results in more than 20 fold reduction in the value of V_{max}/K_M (FIG. 4C, Table 2).

Example 6

Comparison to CaM Binding and Activation of Other Target Enzymes

EF is homologous to CyaA which is an exotoxin secreted by *Bordetella pertussis* (Ladant and Ullmann, 1999). In addition to its N-terminal adenylyl cyclase domain however, CyaA, a 1705 a.a. protein also contains residues responsible for hemolytic activity. Despite an overall sequence identity of only 24%, the residues around the active site are highly conserved between EF and CyaA (FIG. 2). Only two out of fifteen residues that contact the substrate differs between two proteins and these two residues use their main chain, rather side chain atoms to contact the substrate. The conformation of CaM when complexed to EF and CyaA are most likely similar, as both proteins lead to reduced quenching (indicating an extended CaM structure) in a fluorescence resonance energy transfer (FRET) experiment utilizing a CaM mutant having a fluorescence donor (AEDANS) on one lobe and a non-fluorescence acceptor (DAB) on the other (Supplemental material) (Drume et al. 2000). The K_d of CyaA (residue **1-412**) for CaM obtained from fluorescence titration was $10 \mu\text{M}$.

The crystal structures of CaM in complex with fragments from myosin light chain kinase (MLCK) (Meador et al., 1992), CaM kinase II α (CaMKII α) (Meador et al., 1993), CaM kinase kinase (CaMKK) (Osawa et al., 1999) and the Ca^{2+} -sensitive potassium channel (Schumacher et al., 2001) define the canonical view of CaM/effector interaction in which the hydrophobic faces of the two CaM lobes act as a clamp, surrounding a target helix or helices (FIG. 7B and FIG. 7C). The structure of the EF-CaM complex differs dramatically from this view. In the EF-CaM complex, the calmodulin lobes do not serve as a clamp. The overall conformation of

calmodulin is extended rather than compact, and the hydrophobic binding surface of the calcium-free N-terminus is buried within CaM rather than oriented towards the effector target. In spite of these differences, the interaction between the C-terminal lobe of CaM and EF helix H, which harbors 22% of the total CaM-binding surface, is very similar to the interaction observed with recognition helix peptides from MLCK, and CAMKII (Meador et al., 1992; Meador et al., 1993).

Because peptides derived from a number of CaM binding proteins have been used previously to probe the structure of CaM in complex with various CaM-effectors (Meador et al., 1992; Meador et al., 1993; Osawa et al., 1999), the inventors tested the effect of an EF helix H peptide on the conformation of CaM in isolation of the surrounding EF enzyme using the aforementioned FRET technique. The entire catalytic domain of EF causes a decrease in energy transfer efficiency, indicating an extended CaM conformation (Drum et al., 2000). However, a helix H peptide (residues 521-539) causes increased energy transfer similar to an MLCK peptide, indicating a more compact conformation (supplemental material). The apparent dissociation constant of helix H peptide obtained from the titration data was 8.8 μ M, indicating \sim 1000 times weaker affinity than that of intact enzyme. Nonetheless, CaM does interact with the helix H peptide of EF, and the conformation of CaM induced by this peptide clearly differs from the structure of CaM when it is bound to intact EF protein.

Rhoades and Friedberg (Rhoades and Friedberg, 1997) have cataloged over 50 CaM effector molecules based on the presence of positively charged amino acids and characteristic 1-5-10 or 1-8-14 spacings of hydrophobic residues within putative CaM-binding helices. EF was identified as having a 1-8-14 motif, but in the crystal structure the amino acids with this spacing do not interact with CaM. EF helix H contains a 1-5-10 spacing of hydrophobic residues (V529, L533, I538), but these residues are three amino acids out of register when structurally superimposed with the 1-5-10 motif observed in the crystal structure of CaM in complex with a CaMKII peptide. Taken together with our FRET data, these observations underscore the difficulty in predicting CaM conformation and CaM interaction with its targets based on sequence homology and peptide studies.

Similar to EF, CaM makes multiple contacts to several CaM effectors such as ion channels, MLCK, glycogen phosphorylase kinase, Smad, and brush border myosin I (Schumacher et al., 2001; Pitt et al., 2001; Krueger et al., 2001; Swanlung-Collins, 1991; Scherer and Graff, 2000; Trehwella et al., 1990). The structure of the complex of CaM and the gating domain of the Ca^{2+} -activated K^{+} channel reveals that two CaM binding sites within the channel allow CaM to induce the dimerization of the channel to trigger calcium-induced activation (FIG. 7C) (Schumacher et al., 2001). Studies involving caldesmon, phosphorylase kinase, and CAP-23/NAP-22 have implied interactions outside of the classically defined CaM binding surfaces (Trehwella et al., 1990; Farrar et al., 1993; Hayashi et al., 2000; Wang et al., 1997). Recent X-ray scattering data show that in addition to the conventional contact surfaces, the N-terminal end of CaM binds to the C-terminal end of the MLCK catalytic core in order to remove the inhibitory domain of MLCK (Krueger et al., 2001).

Removal of an auto-inhibitory domain, through conformational changes induced by CaM, is a prevalent mechanism for CaM activation of its targets, including a family of kinases, calcineurin, nitric oxide synthase, and phosphodiesterase (Eldik and Watterson, 1998). Consequently, the truncation mutants of these proteins lacking an inhibitory domain are constitutively active (Eldik and Watterson, 1998; Montgomery et al., 2000). Although CaM binding displaces the EF helical domain from a catalytic core, the EF helical domain does not serve as an inhibitory domain. EF without the helical domain is catalytically inactive and less sensitive to CaM activation (Drum et al., 2000). Instead, movement of the EF helical domain from a catalytic core triggers reorientation of switch C which leads to the stabilization of a catalytic loop, switch B.

Example 7

Discussion of Activation of EF by CaM

Anthrax has long been a model for understanding the epidemiology and basic biology of infectious disease (Dixon et al., 1999). When Koch outlined the standard criteria with which to define an infectious agent, *Bacillus anthracis* was the first model organism that met all of 'Koch's Postulates'. Subsequently, Louis Pasteur formed the first recorded vaccine by heating anthrax spores and inoculating livestock. Given the historical importance of prokaryotic toxins to our current understanding of eukaryotic biochemistry, it is fitting that an anthrax protein should help shape our thinking about CaM, one of the most ubiquitous and conserved proteins in vertebrate biology. The structure of EF-CaM is the first instance where a functional effector/CaM entity has been characterized structurally, and the complex has the largest protein-protein interface observed to date (Conte et al., 1999). This study using a combination of structural and biochemical analyses suggests a detailed molecular mechanism for how CaM binds four discrete domains of EF to displace a helical domain and consequently stabilize a catalytic loop. Such understanding of the mechanism in CaM activation of EF gives the first molecular insight into how CaM activates a target. Future structural studies of effector/CaM complexes are likely to unveil a rich repertoire of CaM/effector interactions.

There are a variety of mechanisms whereby activators are known to activate enzymes. In the case of GTPase activating protein of low molecular weight G proteins, the activator contributes catalytic residues directly to the active site (Nassar et al., 1998; Rittinger et al., 1997; Scheffzek et al., 1997). In the case of mammalian adenylyl cyclases, the α subunit of Gs, acting from a distance, stabilizes the assembly of a two-part active site (Tesmer et al., 1999). In the case of CaM kinase/CaM, an autoinhibitory peptide is removed from the active site (Eldik and Watterson, 1998). The activation of EF by CaM may be thought of as an extreme example of yet another activation mechanism; that seen in the activation of GTPase activity of Goc proteins by RGS (Tesmer et al., 1997). In this case, the catalytic machinery is present near the site of catalysis, but is disordered in the inactive state. The most surprising aspect of EF activation by CaM is the fact that the conformational switches associated with activation do not

involve residues that participate in catalysis. The catalytic base, the metal binding site, and all of the amino acids thought to be involved in stabilizing the pentavalent transition state are virtually identical in the active and inactive states of the enzyme. Furthermore, these residues are significantly more exposed to solvent (and substrate) in the inactive state than in the active state. The inventors structural and biochemical work indicates that the switch that gives rise to 1000 fold enzyme activity involves residues which bind and position the substrate, not those that perform the catalytic reaction.

EF-like adenyl cyclase exotoxins are found in three pathogens which pose significant human health threats. *B. pertussis* infections have seen a recent rise due to relaxed immunization. *P. aeruginosa* is a predominant mortality risk for hospitalized patients. *B. anthracis* presents an infectious challenge to third-world countries and has been developed as a biological weapon. The structure of EF-CaM indicates that the catalytic sites of these three bacterial enzymes are highly conserved but significantly different from the active site of mAC. Thus, the EF-CaM structure will provide a good starting point for future, structure-based inhibitor design efforts aimed at these human pathogens.

Example 8

Purification of H6-EF3, EF3-CH6 and Calmodulin

The adenyl cyclase domain of EF (291-800) was engineered with a hexahistidine tag on either its N- or C-terminus under the control of a prokaryotic Trc promoter, named H6-EF3 and EF3-CH6, respectively. The purification of EF3-CH6 and H6-EF3 (both pI=8.9) was performed with modifications to that described (Drum et al., 2000). Briefly, crude *Escherichia coli* (*E. coli*) lysate was flowed over a DEAE column to remove acidic *E. coli* proteins and directly onto a Macro-S column. A salt gradient was then applied only to the Macro-S column and the peak fraction containing EF3 pooled. The enriched EF3 was loaded onto a nickel-chelating sepharose column and eluted with 100 mM imidazole (pH 7.0). The greater than 95% pure EF3 protein was then further purified with a Pharmacia Source-S column. The purity of the resultant Edema Factor was greater than 98% and was concentrated to greater than 40 mg/ml. The protein could be stored at -8° C. in 10 mM Tris pH 7.5 buffer. Typical yields for a prep of H6-EF3 and EF3-CH6 gave 80 mg and 45 mg from a 12-liter *E. coli* culture, respectively. Purification of calmodulin was carried out through induction of the expression plasmid pAED4-hCaM in *E. coli* BL21(DE3) cells as described (Drum et al., 2000).

Example 9

Crystallization of EF Without Substrate and EF-CaM Without Substrate

In one embodiment, EF-3 proteins with either hexahistidine-tagged N-terminal or C-terminal ends (H6-EF3 or EF3-CH6, respectively) were purified as described. Crystals of EF alone were grown by the hanging drop method. 1 µL of 40 mg/mL H6EF-3 in 20 mM Tris, pH 7.5, 50 mM NaCl, was mixed with 1 µL of a well solution containing 100 mM citric Acid, (pH 5.65, adjusted with NaOH), 15% glycerol, PEG 550 MME at 11.5% w/v, 220 mM NiSO₄, and 2 mM MgCl₂.

Within one to three weeks, crystals with the P2₁2₁2₁ space group were formed as a bundle. The EF alone crystal clusters were surgically separated into the single crystals. The crystals were then equilibrated for 5 minutes in cryoprotectant containing the well buffer with the glycerol percentage adjusted to 30% w/v. Crystals of nucleotide-free EF3-CH6/CaM complex in the 1222 spacegroup were grown and cryoprotected as described with the exception that no ATP analog was added during cryoprotection. Crystals were frozen in liquid propane and mounted in a 100° K nitrogen stream. Data were collected at APS Biocars 14-BM-C (EF alone) and NSLS X25 (EF-CaM complex), and processed with HKL OR Mosflm.

In another embodiment, all crystals of EF3-calmodulin complex were grown by the hanging drop method. The protein solution (2 ml) was mixed in a 1:1 ratio with the crystallization buffer and allowed to equilibrate via vapor diffusion over 500 ml of well solution at 4° C. Crystal-Screen One and Two (Hampton Research) were used to find crystallization conditions for Edema Factor in complex with calmodulin. Initially, a large proportion of the screened conditions produced a large precipitate upon mixing with the protein. In each case where this occurred, the condition was diluted in the well until precipitation was no longer observed in a newly setup drop. Refinement of the initial condition resulted in single crystals that would grow in approximately 3-6 weeks (Table 3). Lanthanide and 3'-deoxy ATP (5 mM), a non-hydrolyzable ATP analog both facilitated crystal seeding and growth. The washed crystals were analyzed by SDS-PAGE and mass spectrometry and appeared to contain EF3 and calmodulin in 1:1 ratio. Although both H6-EF3 and EF3-CH6 could form crystals when mixed with calmodulin, the best diffraction and most regular crystallization kinetic were observed with EF3-CH6, the C-terminal, hexahistidine-tagged protein in combination with calmodulin. For heavy metal derivatization, the crystals were soaked with saturated uranium fluoride for 30 min or 10 mM tri-ethyl lead acetate for 2 hours. The approximately 0.4×0.4×0.6 mm-size crystals were transferred into an identical mother-liquor containing 30% glycerol by slowly ramping from the initial glycerol concentration to 30% glycerol over a period of 10 hours and allowing the crystal to soak in the 30% glycerol solution for greater than 12 hours. The crystal was then frozen in liquid propane and data collected at 100K (Table 4). Although many surface fissures were observed on the crystal, x-ray analysis showed relatively low mosaicity and increased diffraction strength compared with similar crystals that were cryo-protected with faster exchange times.

TABLE 3

Crystallization conditions for the crystal forms of EF/calmodulin complex			
	I222	P3 ₁ 21	P2 ₁ 2 ₁ 2 ₁
14.6 mg/ml EF3	EF3-CH6	EF3-CH6	H6-EF3

a For the native data set, 1200 of data was collected in 0.50 oscillations with two kappa angles separated by 40°. Data was then collected with short exposures to compensate for the multiple overloads observed in the low-resolution reflections.

^bRmerge statistics were generated using SCALEIT (Smith et al., 1992).

^cCalculated using SHARP (La Fortelle et al., 1997).

Example 10

Cryoprotection of EF3-CaM Complex

The approximately 0.4×0.4×0.6 mm-size crystals were transferred into an identical mother-liquor containing 30% glycerol by slowly ramping from the initial glycerol concentration to 30% glycerol over a period of 10 hours and allowing the crystal to soak in the 30% glycerol solution for greater than 12 hours. The crystal was then frozen in liquid propane and data collected at 100K (Table 3). Although many surface fissures were observed on the crystal, X-ray analysis showed relatively low mosaicity and increased diffraction strength compared with similar crystals that were cryo-protected with faster exchange times.

Example 11

Data Collection and Processing for EF3-Calmodulin Complex

For the data of EF3-CH6/selono-methionyl calmodulin, an EXAFS study was used to find the selenium K edge before data were collected at inflection point, peak, and remote wavelengths. Initially, the selenium edge was obscured by background fluorescence from the arsenic moiety of 100 mM cacodylic acid, included as the cryoprotectant buffer. However, narrowing of the band pass of the fluorimeter to selectively amplify the selenium fluorescence allowed accurate tuning of the monochromator to the selenium edge. The native data was reduced with MOSFLM (Leslie, 1992), data from the uranium fluoride soak with HKL (Otwinowski et al., 1997), data with seleno-methionyl calmodulin with HKL

2000 (Otwinowski et al., 1997), and data from the tri-ethyl lead acetate soak with XDS (Kabsch, 1993).

Example 12

Results and Discussion of EF3-Calmodulin Complex

Minor changes in crystallization conditions produced crystals of three distinct space groups, I222, P3121, and P212121 (Table 3). Crystals of space group I222 (Table 4) were used for the structure determination because they were the most reproducible and were less often twinned than the other space groups. The EF/calmodulin crystals with p3121 space group have unit cell dimensions of a=b=172.3 Å, c=196.8 Å and that of P212121 has a unit cell dimension as a=183.5 Å, b=217.3 Å, c=322.9 Å. The assumption of three Edema Factor/calmodulin complexes (228 kDa) in I222 and P3121 asymmetric units, yields a V_M of 3.6 and 4.0 Å³, respectively (solvent content of ~65% and 70%). A similar V_M and solvent content (3.3 Å³ and 62%) predicts twelve EF3/calmodulin complexes in P212121 space group. The presence of several distinct space groups produced by similar crystal conditions suggested a relationship between crystallographic operators and predicted a three-fold non-crystallographic symmetry operator parallel to the b-c diagonal of the I222 space group. A self-rotation function search in the I222 space group reveals a significant peak in the k=120° section at the expected position, confirming the presence of a non-crystallographic three-fold axis in the asymmetric unit (FIG. 8).

The inventors grew crystals from the complex of EF3 and seleno-methionyl calmodulin (Table 4). Calmodulin contains 9 methionines while EF3 has only 3. Selenium incorporation was confirmed by the existence of a peak in the self-rotation function calculated using anomalous difference Patterson

maps. This peak was in roughly the same position as that seen in the self rotation function using only native data. After numerous unsuccessful attempts to interpret the anomalous and isomorphous difference Pattersons using HASSP, RSPS (Knight, 2000) and SOLVE (Terwilliger et al., 1999), a direct methods algorithm, Shake-n-Bake (Weeks et al., 1999), was applied to the anomalous differences. Truncating the data at 4 Å and applying an $E/\sigma E$ cutoff of 1, allowed the successful location of 8 of the expected 27 seleniums, resulting in a ratio of 1 resolvable selenium per 167 amino acids. Additional, potential sites located using difference Fourier maps were filtered based on the relative positions of the methionines within a previously solved calmodulin structure (Babu et al., 1985) and the expected three-fold symmetry within the asymmetric unit. After 12 selenium sites had been identified, the solvent flattened phases produced significant peaks in cross Fourier maps from data of crystals soaked with either uranium fluoride or tri-ethyl lead acetate (Table 4), corresponding to 5 U and 5 Pb sites. Using SHARP (La Fortelle et al., 1997), an experimental, 4 Å map was calculated and solvent flattened with DM (Cowtan, 1994).

Due to the poor quality of the initial experimental phases, map averaging was required to identify the remaining 22 heavy atom sites. After skeletonization of the density in MAPMAN (Kleywegt et al., 1999), a mask was drawn around each monomer using MAMA (Kleywegt et al., 1999) and operators relating the three enzymes were refined with IMP (Kleywegt et al., 1997). Maps were rotated and averaged using MAPROT (Stein et al., 1994) and SIGMAA (Read, 1986) was used to combine the back-transformed phases with the original, experimental phases. The improved phases were used to find the remaining 15 Se, 4 U and 3 Pb sites in cross difference Fourier maps, resulting in an overall Figure of merit (FOM) of 0.63 for acentric reflections. A section from FOM-weighted F_o map without density modification is shown in FIG. 8. The resultant, refined operators were used as starting points for eventual iterative averaging, solvent flattening and phase combination and extension from 4 Å to 2.75 Å using DM (Cowtan, 1994).

Although objective evaluation of experimental phases can be difficult, several factors point to the validity of experimental phasing. Unaveraged phases determined from the refinement of all 47 identified heavy atom sites yielded an overall FOM of 0.63 and phasing power and Cullis R statistics for each derivative are listed in Table 2. In the resulting map, electron density with clear secondary structure features is visible and three-fold symmetry is visible within the A.S.U. (FIG. 9), unique from any expected crystallographic symmetry axis and consistent with the solution to the native self-rotation function.

Example 13

Structure Determination and Refinement of EF and EF-CaM

The EF-alone structure was determined by molecular replacement, using the program EPMR and data from 15-4 Å (Table 1). The coordinates for amino acids **294-643** of EF from a preliminary model of EF in complex with CaM and 3'dATP were used to determine initial placement of the single molecule in the asymmetric unit. Holding this solution fixed, amino acids **660-790** were then placed as a rigid body, yielding an overall R-factor of 59% and correlation coefficient on F's of 25%. A single round of rigid body, B-factor and simulated annealing refinement using CNS resulted in working and free R values of 46% and 49%, respectively. The remain-

ing residues were modeled, and the structure was refined using the programs TURBO-FRODO, O, and CNS. The initial solution for the structure of EF-CaM without ATP analog was determined by transferring EF-CaM/3'dATP coordinates that do not have nucleotide or the nucleotide contacting residues onto the EF-CaM data set. The initial working and free R values were 37% and 44% after simulated annealing refinement in CNS. Additional model building was performed using the program O and iterative cycles of B-factor and simulated annealing using a non-crystallographic three-fold restraint were performed using CNS (Brunger et al., 1998). Calculation for the surface areas was done by using GRASP (Nicholls et al., 1991). Figures were made using Molscrip, Povray, GRASP, and David Jeruzalmi's r3dtopov and loosengrasp (Esnouf, 1999; Nicholls et al., 1991).

In another embodiment, two crystal forms of the EF/CaM complex with space group I222 and P3₁21 were grown and used in solving the structure (Drum et al., 2001). Both crystal forms contain three complexes in the asymmetric unit, and are related to one another such that the crystallographic symmetry in one space group is closely related to the non-crystallographic symmetry in the other. The best crystals, those of space group I222, diffract to 2.75 Å resolution. The structure was initially solved by multi-wavelength anomalous diffraction (MAD) at 3.8 Å resolution using the signal from the 27 CaM selenomethionines and three Yb²⁺ ions in the asymmetric unit. The initial phase set was improved by inclusion of 4.0 Å uranyl fluoride and triethyl lead acetate derivative data. The 3.8 Å experimental phases were extended to 2.75 Å resolution using iterative cycles of three-fold non-crystallographic symmetry averaging and phase combination in DM⁵⁸. The initial phases for the EF-alone and EF-CaM structures were obtained by molecular replacement using the program EPMR. The residues were modeled, and the structure was refined using the programs TURBO-FRODO, O, and CNS. Calculation for the surface areas was done by using GRASP. The structure was traced using Turbo and O (Jones et al., 1991). Iterative cycles of B-factor and simulated annealing using a non-crystallographic three-fold restraint were performed using CNS (Brunger et al., 1998). Calculation for the surface areas was done by using GRASP (Nicholls et al., 1991). Figures were made using Molscrip, Povray, GRASP, and David Jeruzalmi's r3dtopov and loosengrasp (Nicholls et al., 1991; Kraulis, 1991). The search for the structure homolog of EF C_A and C_B domains was performed using NCBI VAST search engine (Gibrat et al., 1996) and the top thirty returns were examined manually.

Example 14

Construction and Analysis of EF Mutants

To construct the plasmids for the expression of mutant proteins, pProExH6-EF3 was used as the template, and the desired mutation was introduced using the Stratagene Quik-Change kit. The resulting mutation was confirmed by DNA sequencing using Perkin Elmer Big-Dye kit. Plasmids for each mutation were then transformed into the RNaseE deficient *E. coli* BL21 Star™ (DE3) containing pUBS520 and mutant proteins were purified to greater than 90% pure as described (Drum et al., 2000). In vitro adenylyl cyclase assays of the purified were performed using α -³²P-ATP as described (Drum et al., 2000). To ensure that the observed changes in adenylyl cyclase activity of the purified mutant proteins is not due to the clonal variation, two independent plasmid clones for each mutation were then transformed into *E. coli* BL21 Star™ (DE3) containing pUBS520 and the high

speed supernatants of *E. coli* lysate prepared. In vitro adenylyl cyclase activity of the EF mutant proteins was performed. In all cases, two independent mutant proteins behave similarly.

Example 15

A Structural Homologue of EF/CaM

Whereas EF is not homologous to the catalytic core of mAC, each of the four domains of EF/CaM has a structural counterpart within a previously solved complex: that of the tyrosine kinase regulator, Cb1, bound to a ubiquitin conjugating enzyme, Ubc-H7 (FIG. 10) (Meng et al., 1999). EF domain C_B shares structural homology with UbcH7 (2.9 rmsd over 49 aa residues), the C_A domain with the SH2 domain of Cb1 (3.0 rmsd over 50 aa residues), the C-terminus of CaM with the Cb1 calcium binding domain (2.6 rmsd over 61 aa residues), and the helical domain of EF with the helical domain of Cb1 (2.3 rmsd over 48 aa residues). While the interaction of the C-terminal domain of CaM with the helical domain and the C_B domain of EF is reminiscent of Cb1, the contact between UbcH7 and the SH2 domain of Cb1 is significantly different from that of the C_A and C_B domains of EF. These two complexes may share a common, ancestor protein in which homologs of these domains are part of a single polypeptide chain. Alternatively, the connection among these four domains may represent a motif for the interaction of these four domains. Also, the homology between C_A and the SH2 domain raises the possibility that EF or its ancestors may interact with tyrosine-phosphorylated eukaryotic proteins.

Example 16

Purification of CyaA and Fluorescence Resonance Energy Transfer of Labeled CaM

The expression and purification of recombinant EF and calmodulin protein were performed as described previously (Drum et al, 2000). To express the adenylyl cyclase domain (amino acids 1-412) of CyaA, pET-CyaA1-412 (kindly provided by Dr. Emanuel Hanski at Hebrew Univ.-Hadassah Medical School) (Bejerano et al., 1999) were transformed into *E. coli* B834(DE3) cells harboring pREP4. The resulting cells were cultured at the optimized condition for CyaA expression (19-hour induction at 24° C. with 30 mM IPTG) and the high-speed supernatant of *E. coli* lysate was prepared without denaturant. Recombinant CyaA1-412 with greater than 95% purity was obtained by fractionation through a Ni-chelating column followed by a Q-sepharose column, concentrated to greater than 10 mg/ml, and stored at -80° C. The identity of CyaA1-412 was confirmed by its molecular weight (46,216 daltons based on mass spectrometry, 32 daltons higher than its ideal mass) and its calmodulin-activated adenylyl cyclase activity. The yield is around 12 mg from each liter of *E. coli* culture. To perform the FRET study, CaM34/110, a human CaM mutant in which T34 and T110 were both changed to cysteine was randomly labeled with a fluorescence donor, N-iodoacetyl-N'-(5-sulfo-1-naphthyl)ethylenediamine (1,5-IAEDANS) and a non-fluorescence acceptor, 4-dimethylaminophenylazophenyl-4'-maleimide (DAB) and purified by HPLC. The steady-state fluorescence emission of CaM34/110-AEDANS/DAB was recorded as described (Drum et al., 2000). The dissociation constant between CaM and CyaA and between CaM and the EF helix H peptide was determined by titration of donor-acceptor labeled CaM34/110 with CyaA1-412 protein and EF H peptide, respectively (Drum et al., 2000).

Example 17

Expression of the Catalytic Domain of Edema Factor and CaM

The inventors have developed a novel purification scheme to facilitate large-scale production of Edema Factor. The approach begins with modifications of the Edema Factor gene that replaced the binding region of protective antigen with a hexahistidine tag. Activity of this truncated molecule was probed using an adenylyl cyclase assay. As expected from previous studies (Masure et al., 1991; Masure et al., 1988), the truncated protein had wild-type cyclase activity, which was stimulated upon complex formation with Ca^{2+} /CaM. The gene encoding Edema Factor was ligated into a modified pProEx-1 expression vector (Gibco/BRL) to construct expression plasmids coding for the protein with either N- or C-terminal hexahistidine tags. Progressive deletion of residues from the N- and C-termini was performed to search for the optimal construct for the expression of the functional, CaM-sensitive adenylyl cyclase. Deletion of about 300 amino acids from the N-terminus significantly improved the expression of Edema Factor, and its expression could be clearly visualized after the whole-cell lysate was run on a gel under the optimum induction conditions (100 uM IPTG over 12 hours in enriched media at 25 deg.). The induced lysate was first loaded onto DEAE column at pH 7.5. Due to the relative basic pI (8.9) of the Edema Factor, most of the desired protein flowed through the column, which was then loaded onto an S-sepharose (Pharmacia) column. Functional Edema Factor was eluted with a NaCl gradient, loaded onto a nickel-NTA column and eluted with 150 mM imidazole. Eluate from this procedure contained greater than 97% pure Edema Factor, with a small amount of proteolytic contamination as judged by SDS-PAGE and mass spectroscopy. Total yield was approximately 42 mg/L culture, about 10 fold better than that reported previously (Labruyere et al., 1990). Anticipating crystal packing problems that may arise from disordered histidine residues, a C-terminally tagged protein was also constructed and purified via the same strategy. Its yield was lower, 12 mg/L culture, though the proteolytic contamination was mildly reduced.

Full length human and fruit fly CaM's were expressed in bacteria and purified using a previously published protocol (Huber et al., 1996). The major step in the purification of CaM is a hydrophobic interaction column, phenyl sepharose, which has high affinity for CaM in the presence of calcium ion and drastically reduced affinity in the absence of calcium ion. *E. coli* were disrupted by sonication, and the centrifuged lysate was loaded on a phenyl sepharose column in the presence of calcium. The column was then washed and CaM was eluted with EDTA or EGTA. The eluate was greater than 95% pure. For x-ray crystallography, the eluate is further purified using an ion exchange column (DEAE or Q-sepharose). This procedure yields ~5-10 mg purified protein per liter of culture.

What is claimed is:

1. A method of assaying for an inhibitor of infection by a bacteria comprising:

selecting a potential inhibitor of a calmodulin activated adenylyl cyclase exotoxin by modeling the inhibitor using structural coordinates of a calmodulin activated adenylyl cyclase exotoxin;

obtaining the selected potential inhibitor;
obtaining a calmodulin activated adenylyl cyclase exotoxin;

obtaining calmodulin;

admixing the potential inhibitor, the exotoxin, and the calmodulin; and

assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin.

2. The method of claim 1, wherein the bacterial infection is *Bacillus anthracis*, or *Bordetella pertussis*.

3. The method of claim 1, wherein the calmodulin activated adenylyl cyclase exotoxin is Edema Factor from *Bacillus anthracis*.

4. The method of claim 1, wherein the potential inhibitor is a protein, a small molecule, a modified nucleotide, or an antibody.

5. A method of assaying for an inhibitor of infection by a bacteria comprising:

selecting a potential inhibitor of an adenylyl cyclase exotoxin by modeling the inhibitor using structural coordinates of a calmodulin activated adenylyl cyclase exotoxin;

obtaining the selected potential inhibitor;

obtaining an adenylyl cyclase exotoxin;

admixing the potential inhibitor and the exotoxin; and assaying to determine whether or not the potential inhibitor inhibits production of cAMP by the exotoxin.

6. The method of claim 5, wherein the bacterial infection is *Pseudomonas aeruginosa*.

7. The method of claim 5, herein the adenylyl cyclase exotoxin is a homolog of *Bacillus Anthracis* Edema Factor from *Pseudomonas aeruginosa*.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 7,462,472 B2
APPLICATION NO. : 10/286452
DATED : December 9, 2008
INVENTOR(S) : Wei-Jen Tang and Andrew Bohm

Page 1 of 1

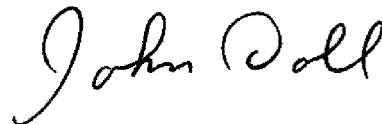

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

In title page, item (73) Assignees, line 3, delete "MD" and insert --MA-- therefor.

In claim 7, column 46, line 54, delete "herein" and insert --wherein-- therefor.

Signed and Sealed this
